The question—How shall public health instruction be made available for health workers?—is perplexing. It is not yet practicable to restrict employment to health workers who have diplomas. Lawyers, doctors, and teachers, after going through transition periods, finally found it feasible to limit practice to those who meet legal tests as to preparation. When this stage may be reached in public health one can only guess. Certainly it is not near at hand. Eligibility qualifications in this new field will be difficult to enforce until there are more candidates for positions than there are positions. Present conditions as to compensation and security of tenure are too unsatisfactory to attract the best class of young men and women to public health work. Moreover, many of those now engaged in this work are not very promising persons. Many are not qualified to take university courses in public health because their basic education would not enable them to meet admission requirements or to carry college work. Many also have passed the age for successfully taking courses even if they had the necessary foundation. There is no

record available of the ages of nurses and inspectors in public health work, but it has been found that the average age of 225 full-time city health officers is 51 years, and the average age of 483 county health officers is 47 years. Of these 708 full-time health officers, only 102 are under 35; 68 are 35-40; 207 are 41-50, and 331 over 50. If the ages of the medical officers are to any degree indicative of the ages of the nurses and inspectors, it is obvious that the first step in approaching eligibility standards will involve the restricting of new appointments and replacements to young persons whose basic education is equal at least to university admission requirements.

Efforts to make it possible for young and capable health workers to have the advantages of university courses in public health have met with some success. Voluntary health agencies have granted fellowships in public health, covering tuition, travel, and living expenses. The health agencies themselves, recognizing that the problem is so large that private agencies would be barely able to scratch its surface, have in a few instances adopted a policy of giving study leaves with full or part pay to qualified employees. The potentialities for further development in this direction are large, but not large enough to meet the urgent problem of trained personnel with which health departments are now confronted.

Some training of field workers has been attempted by the technical and administrative staffs of the central health organizations, but this semi-tutorial instruction is expensive and irregular and interferes with routine work. In a few states the practical training of new or inexperienced personnel has been systematized. Training stations have been established. An experienced and university trained health officer, nurse, and inspector are assigned to the station—which is usually an efficient county department of health—to give the instruction. Small groups of physicians, nurses, and inspectors are admitted to the station for courses of from 6 to 12 weeks. These students observe efficient work and take part in it; they are taught by capable teachers who also appraise them as to aptitude. Their living expenses are paid by the state department, which frequently secures from private sources a part of the funds required for this purpose and also a part of the salaries of the instructors.

Alabama, Mississippi, Michigan, Missouri, and Tennessee have operated training stations during the past year or longer. The results are reported to be satisfactory. Aside from the teaching, these ably staffed county health organizations develop and demonstrate health procedures of a high order. They test the value of

established measures and improve them or develop better ones. Usually they carry on at least one epidemiological field study.

Thus it will be seen that although ideal conditions for supplying the best kind of health instruction for personnel are not uniformly available, the problem for the workers, in certain states at least, is gradually being simplified, and a foundation for suitable eligibility requirements is being laid.

The outlook for the future may be regarded as mildly encouraging. In normal times, funds for health work are obtainable somewhat more easily than formerly. A few trained workers are gradually infiltrating into the public health structure. The idea of trained personnel is gaining headway slowly in official and in lay circles. These developments are occurring in all the essential branches of public health service especially including that for child health.

#### SUMMARY

1. Public health training is needed for health officers, nurses, and inspectors of the local health services and for the administrative and technical experts of the central organizations.

2. These workers should be taught the subjects included in leading university courses in public health work and administration.

3. The instruction should be supplied by the universities; but as the present situation cannot be met in this way alone, the larger health organizations find it necessary to operate training stations.

4. The cost of training cannot be met as yet by the employees or candidates for positions. In a few instances it is being assumed by the state health departments, with such aid as they can obtain from private agencies.

5. Rigid eligibility requirements for health personnel cannot yet be enforced, except possibly as to age and academic education of new appointees; but progress in laying a foundation for suitable standards in the future is being made.

# Incidence of Sub-Clinical Mastitis\*

G. J. HUCKER, PH.D.

*New York State Agricultural Experiment Station, Geneva, N. Y.*

DURING recent years there has been a growing tendency to attribute an important public health significance to infections of the udder, particularly those due to a streptococcus. The relationship between septic sore throat epidemics and udders infected with streptococci has been one of the principal factors in focusing attention of public health officials upon this type of infection. Milk control officials have been interested not only because of the disease producing possibilities but also on account of the difficulty in actually reducing the number of organisms in milk from infected udders to an acceptable minimum.

The use of terms involving infections in the udder has become somewhat confusing. The term "mastitis" has been roughly applied to all types of udder infections with no consideration of the degree or type. At the outset it should be understood that a discussion of mastitis does not of necessity include the problem of the milk-borne septic sore throat epidemic. Udders harboring organisms responsible for these epidemics have probably become contaminated from a human source with a type of streptococcus distinct from those found in other forms of mastitis. Udders infected with the mastitis type of streptococcus may never be involved. In other words, ordinary mastitis is not the cause of epidemic septic sore throat. On the other hand, infection with *Streptococcus epidemicus* or *S. pyogenes* may produce the same pathologic and clinical picture in the udder as infections (mastitis) caused by the more common bovine streptococci. This discussion does not include udders infected with the human type of streptococcus.

Mastitis brought about by bovine streptococci, and possibly in some instances micrococci, may be found in two or three clinical forms. The *acute* or *clinical* type is relatively uncommon. The symptoms include an extreme toxic condition, with swollen and highly inflamed udder. The cow is prostrated. Little or no milk can be drawn from the offending quarter. A purulent discharge is usually

\* Read at a Joint Session of the Laboratory and the Food, Drugs and Nutrition Sections of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 16, 1931.

present. A distinct rise in temperature is noted. No special methods of detecting this type of infection are necessary as the condition is obvious.

In contrast to the acute or clinical mastitis is the more common *sub-clinical* type, in which the cow may appear practically normal. There is no toxemia, little or no rise in temperature, and the udder may not show any swelling or inflammation. The milk may be normal in appearance with the possible exception that a few flakes may be seen when strained through fine gauze or wire screens. In aggravated cases pus may be present. A "watery" condition of the milk may be noted in certain instances. The cow appears normal and remains in the milking line. The incidence of this sub-clinical type of mastitis or low grade infection of the udder is the subject of this discussion.

To secure information as to the prevalence and importance of sub-clinical mastitis, two or three samples of milk were secured at intervals from each quarter of approximately 200 cows. These were submitted to the usual laboratory examinations for the detection of mastitis, *i.e.*, cell count, reaction (brom-thymol-blue), amount of lactose, chlorides and catalase present and plating upon veal infusion as well as blood agar. The samples were also incubated over night at 37° C. and examined microscopically for long chained streptococci.

A manual examination was made by a competent veterinarian of each cow, to determine the presence of fibrosis or induration of the udder. Subsequently approximately all were examined post-mortem, and the presence of fibrotic and indurated tissue as well as of pus pockets was noted in the udder.

Of the milk from 439 quarters, 48 per cent showed streptococci (Table I) as evidenced by the presence of streptococcus-like colonies on veal infusion and veal infusion horse blood agar plates. These varied from a few hundred colonies per c.c., to a maximum, in one instance, of over 5,000,000 per c.c. The greater proportion of the quarters carrying streptococci showed less than 100,000 per c.c. Only

TABLE I  
NUMBER OF QUARTERS OF COWS WITH NO CLINICAL EVIDENCE OF MASTITIS, WHICH CARRIED STREPTOCOCCI

<i>Number of Streptococci</i>	<i>Number of Quarters</i>	<i>Per cent of Quarters</i>	<i>Per cent of Quarters Showing Pus upon Post-mortem</i>
No streptococci	239	52	2
Streptococci present	200	48	17.5
Less than 10,000 per c.c.	71	16	
10,000 to 100,000 per c.c.	83	20	
More than 100,000 per c.c.	46	12	

Total quarters which showed pus=9 per cent.

12 per cent of the total number of quarters studied carried streptococci in larger numbers than 100,000 per c.c.

A post-mortem study of the quarters which showed streptococci in any number in the milk indicated that nearly 18 per cent showed pus, against only 2 per cent of those of the milk which showed no streptococci. In only 9 per cent of all quarters examined could pus be found upon autopsy.

Further study of the quarters which showed no streptococci by the use of cultural methods indicated that, by direct examination of the incubated milk, in certain instances long chain streptococci could be demonstrated. It is of interest to know that these particular quarters which showed streptococci upon microscopic examination and did not evidence any streptococcus-like colonies upon agar plates were found to contain pus upon post-mortem. With few exceptions the milk from all quarters which showed pus post-mortem showed streptococci either culturally or microscopically.

It has become common practice among veterinarians to detect the presence of abnormal tissues by manipulation of the udder. These are usually fibrotic or indurated. The presence of this fibrosis and induration has been interpreted by those who lay stress upon physical

TABLE II  
NUMBER OF QUARTERS SHOWING FIBROSIS UPON POST-MORTEM

	<i>Number</i>	<i>Per cent</i>	<i>Per cent Showing Pus upon Post-mortem</i>	<i>Per cent Showing Streptococci in Milk</i>
Marked fibrosis	298	66	14	37
Slight fibrosis	52	10	4	41
Normal	78	24	1+	22

examinations as indicating the presence of mastitis. A study of 428 quarters (Table II) which had been subjected to careful physical examination indicated that approximately 76 per cent showed fibrosis to some degree. Subsequent post-mortem indicated that, with very few exceptions, the results of physical examination could be confirmed by autopsy findings, showing that fibrosis and induration of the udder may be accurately detected by a competent veterinarian. The significance of this fibrosis, however, is still a debatable question.

Only 24 per cent of all of the quarters examined failed to show fibrosis or induration. Of the 24 per cent non-fibrotic udders only 1 per cent showed pus upon post-mortem, while 22 per cent showed streptococci in the milk. On the other hand, of the quarters which were fibrotic to some degree, 18 per cent showed pus upon post-mortem, and 78 per cent streptococci in the milk.

TABLE III

NUMBER OF INDIVIDUAL COWS WITH NO CLINICAL EVIDENCE OF MASTITIS WHICH CARRIED STREPTOCOCCI

<i>Number of Quarters</i>	<i>Number of Cows</i>	<i>Per cent of Cows</i>	<i>Per cent of Cows Showing Pus in One or More Quarters upon Post-mortem</i>
No streptococci in any quarter	26	22	2
Streptococci in one or more quarters	92	78	25
Streptococci in one quarter	40	34	17
In two quarters	35	30	25
In three quarters	13	11	34
In four quarters	4	3	25

Cows showing pus (post-mortem) in one or more quarters=21 per cent.

It has been intimated by certain investigators that a large percentage of cows harbor pus pockets in the udder, the organisms from which may be thrown off intermittently into the milk supply, and unless regular examinations are made these pus pockets may remain undetected.

An autopsy examination of 560 quarters showed that slightly more than 9 per cent contained pus pockets. On the other hand, 21 per cent of the cows (Table III) studied showed pus post-mortem in one or more quarters. The detection of these animals by cultural methods proved to be extremely unsatisfactory. Of 151 quarters in which pus was found post-mortem, only 20 per cent showed streptococci in the milk, and approximately 35 per cent gave no indication by chemical tests, viz., amount of chlorides and lactose, that the milk might be abnormal. In other words, more than half of the quarters which on autopsy were found to harbor pus pockets were secreting milk which gave no evidence of the presence of pus in the udder tissues by cultural examination.

It has been thought that the presence of fibrosis and induration in the udder indicates an infection. A study of 440 quarters (Table IV) showing fibrosis indicated that 78 per cent showed streptococci in the milk. In other words, 22 per cent of all the quarters which showed fibrosis to some degree failed to show streptococci in the milk,

TABLE IV

RELATION OF QUARTERS WHICH CARRIED STREPTOCOCCI TO THE PRESENCE OF FIBROTIC TISSUE UPON POST-MORTEM

<i>Number of Streptococci</i>	<i>Number of Quarters</i>	<i>Per cent of Quarters Showing Fibrosis</i>		<i>Per cent Showing No Fibrosis</i>
		<i>Marked</i>	<i>Slight</i>	
No streptococci	236	54	13	32
Streptococci present	204	62	16	21
Total	440	58	14	27

TABLE V

INCIDENCE IN HERDS OF FIBROSIS AND PRESENCE OF STREPTOCOCCI

<i>Herd</i>	<i>Number of Cows</i>	<i>Per cent of Quarters Showing Fibrosis upon Post-mortem</i>	<i>Per cent of Quarters which Showed Streptococci</i>
I	14	66	
II	12	78	
III	26	98	48
IV	17	80	36
V	10	65	60
VI	14	75	48
			35

which indicates that fibrosis does not necessarily signify the presence of an active infection. It is more reasonable to assume that this fibrosis and induration is the result of infection rather than an indication of the presence of infection. The presence of these abnormal tissues indicates either a *present* or *past* infection.

Physical examination of 221 cows from a typical dairy district showed that only 7 per cent did not give evidence of some degree of fibrosis or induration in 1 or more quarters. Further study of this 7 per cent also revealed that all of the remaining cows, with 1 exception, either carried streptococci or showed pus upon post-mortem in 1 or more quarters. In other words, only 1 of 221 cows studied was found to be free from fibrotic tissue, pus, or streptococci in all 4 quarters. Further tests no doubt would indicate some type of abnormal condition in one of the quarters of this remaining "normal" cow.

In certain instances (Table IV), as high as 98 per cent of all of the individual quarters in herds were found either to carry streptococci or show the presence of fibrotic tissue in the udder.

#### CONCLUSION

Sub-clinical mastitis is relatively common and without careful laboratory control or veterinary inspection may remain undetected. Physical examinations, supported by autopsy observations, indicate that as high as 98 per cent of the quarters in certain herds may show fibrosis or induration. This condition probably signifies previous as well as present infection.

In nearly one-half of all of the quarters studied streptococci could be demonstrated by cultural or microscopic methods, the percentages being greater in quarters showing fibrosis.

Approximately one-fifth of the 221 cows autopsied showed pus pockets in the udder. The milk secured from these animals prior to autopsy gave no indication, culturally, in more than one-half of the cases, that the udder might be abnormal.

# Postgraduate Study in Child Hygiene in the United States and Canada\*

RICHARD M. SMITH, M.D.

*Pediatrician, Boston, Mass.*

IN order that I might inform myself accurately with reference to the opportunities for postgraduate study in child hygiene in the United States and Canada, I have written to all the medical schools offering postgraduate courses and to the schools of public health. I was surprised to find in studying the replies to the letters, and in investigating the catalogues and announcements which were sent to me, that the opportunities for postgraduate work in child hygiene are extremely limited.

Most of the medical schools as a part of the undergraduate work in connection with the department of pediatrics give some instruction on the care of well children and give the students a chance to observe the work of so-called well baby clinics. A number of medical schools also offer postgraduate courses in pediatrics which include the same type of instruction in the care of well children. Very few of the schools go further than this, and none offers complete systematic courses in child hygiene. Undoubtedly one's knowledge of certain aspects of child hygiene would be furthered by taking a postgraduate course in pediatrics in any one of the many well recognized medical schools. These courses, however, cannot be considered in any sense courses in child hygiene, and therefore no attempt has been made to analyze the instruction given. This matter has been thoroughly presented in the report on pediatric instruction prepared by Dr. Borden Veeder for the White House Conference on Child Health and Protection.

If we turn next to the schools of public health we find that there is a surprising lack of systematic instruction in child hygiene. There are courses offered which cover certain aspects of the subject, but complete courses are given in only 2 schools, Johns Hopkins and Harvard. In various universities courses are offered which present certain aspects of child hygiene.

\* Read before the Child Hygiene Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 17, 1931.

At Yale, in the School of Bacteriology, Pathology, and Public Health, there is a short elective course on infant welfare which includes lectures and discussions in regard to the technic of the organization of the campaign against infant mortality including prenatal work, administration of infant welfare stations, and public health education as related to infant hygiene. This occupies 2 hours a week during the spring term.

In the Graduate School of Education an opportunity is given through the Yale Psycho-Clinic for research in the field of child development and child hygiene with special emphasis on the period of infancy.

In the course in public health administration considerable time is given in class, and several hours in the field, to child health clinics and to health work in the schools.

There is also a course in school hygiene dealing with the problems of school sanitation and with the objectives and methods of organization involved in the supervision of the health of the school child. This course consists of 2 hours a week for 1 term.

A course in practical field work in public health offers an opportunity for direct clinical experience in various fields of municipal health department activity, and this, of course, includes observation of work in child hygiene.

At the University of Toronto, School of Hygiene, there are clinics on communicable diseases and also students attend well baby and prenatal clinics, but there is no course in child hygiene.

At Columbia University, under the DeLamar Institute, there is a course devoted to preventive medicine and public health administration occupying 1 hour a week for 3 semesters. Also, in the summer session there is a course on school health inspection and school health supervision emphasizing mental hygiene and another emphasizing physical education.

At the University of Minnesota, through its Institute of Child Welfare, there is a course in child welfare leading either to a master's or doctor's degree. Lectures include such subjects as, child training and child psychology, physical development, care and development of the young child, parental education, and mental examination of the preschool child. Courses are held at various times throughout the year and cover quite fully this aspect of the subject. The Institute of Child Welfare offers a particularly fine opportunity for students wishing to do special work in this department of child hygiene.

At the University of Iowa, in the summer courses in child welfare,

there are opportunities for the study of various phases of child hygiene. One course of 5 hours a week for 6 weeks gives an introduction to child development. A second one on nutrition is a series of lectures dealing with the principles of nutrition with special emphasis on their relation to child health and the technics of feeding. There are also several courses on child psychology, one on physical growth, and another on genetics. There are several courses on the social aspects of child hygiene, such as parent education and the child in the home. There are also opportunities for field work in research in physical and mental measurements.

At the Massachusetts Institute of Technology, in the department of biology and public health, there are several courses on health education. A course is given 2 hours a week for the first semester which is a consideration of the procedures and methods used by health and school departments in health education. Practical field work is given to allow the student an opportunity to study and participate in these activities. A similar course is available also as a summer course.

Another course in school health administration, given 1 hour a week during half a year, deals with the organization of the health work expected from teachers, doctors, nurses, physical educators, nutrition workers, and others, presenting the objectives and measurements of accomplishment for each phase of the work.

Boston University offers through its school of education a course on health education 2 hours a week throughout the year, discussing desirable habits, knowledge, and activities with an appreciation of a health education program as a vital part of the school system. A second course, given 2 hours a week, is designed primarily for those interested in working out a coöperative program in health education. A third, given 2 hours a week, deals with the principles and problems in the administration of health education programs. This is a somewhat more comprehensive course designed primarily for graduate students and teachers in active service, and is planned to give lay instruction in such matters as first aid, school feeding, mental hygiene, health teaching in elementary and intermediate grades, physical education, athletics, and so forth.

At Johns Hopkins University, under public health administration, an elective course in child hygiene is offered 2 afternoons a week for half a year, which includes lectures on the historical development of child health work in the United States and in foreign countries and the present purposes and methods of child hygiene activity. There are demonstrations and field work through milk stations, open air schools, schools for correction of defects, tuberculosis, and so forth.

Students are required to attend field demonstrations of child hygiene activities and are assigned topics for study. This is a comprehensive course and covers quite completely the entire range of child hygiene.

At the Harvard School of Public Health there is a course on child hygiene 3 mornings a week for 4 months with field work taking all day for 4 months. This field work is done in conjunction with the course on public health administration. The time of the course is devoted to the general discussion of the subject of child hygiene including a considerable amount of work on normal growth and development. Students are given a chance to observe various phases of child hygiene work, prenatal clinics, postnatal clinics, child welfare clinics, and work among school children, and also with special groups such as the handicapped, feebleminded and blind presented through the work of special institutions dealing with each group. There are also two other elective courses in child hygiene for students who have completed the first course in which intensive work may be had in the various branches of child hygiene or in which research in some particular subject may be undertaken.

From a consideration of the type of instruction offered in the graduate schools of medicine and in the universities and in schools of public health it is obvious that there is a widespread recognition of the importance of work with children and that certain phases of the subject receive adequate presentation. It is equally clear that except in 2 instances there is no evidence of a comprehensive vision of what child hygiene means. It would seem not out of place to state briefly some of the fundamental considerations which should be recognized by anyone who wishes to perfect himself or herself in this phase of public health work.

Child hygiene is the offspring of two definite aspects of medical work. In the first place, it is directly and intimately connected with pediatrics. It has to do with everything which concerns the well child, especially with normal growth and development and their determining factors. In the second place, in its practical aspects it is an important department of public health administration. It is, of course, true that a great deal of valuable child hygiene work has been and is being done under auspices other than public health authorities, federal, state, or municipal, but, nevertheless, from an organization point of view it is and should be a part of organized public health work.

Because of this double origin of child hygiene it follows that the leaders in child hygiene must have adequate training in both pediatrics and public health administration with its related subjects

of vital statistics and sanitary engineering. In the past child hygiene has been inadequately taught in our medical schools and its importance insufficiently recognized in pediatric departments. Fortunately at present almost all of the pediatric departments in the medical schools in this country and Canada recognize the importance of child hygiene or preventive pediatrics, as it is frequently called, and students receive a considerable amount of, although necessarily inadequate, instruction in this phase of work with children.

There is obviously a need for more comprehensive courses in child hygiene in connection with the postgraduate departments of medical schools and universities and the schools of public health. Distinct child hygiene departments should be established which would develop opportunities for study of the whole field.

From an administrative point of view in the past the direction of child hygiene work has been intrusted too often to lay persons whose only qualifications were based upon interest in and sympathy for children, or to trained nurses who have had no more special training in work with children than is given in a small children's ward in a general hospital. The time has passed when child hygiene can be linked in administrative work, with public health nursing, or any other division of a public health department. Child hygiene deserves a division of its own presided over by an adequately trained physician who has had special postgraduate work in pediatrics and additional training in public health administration. Until the important positions in child hygiene are filled by persons of such training child hygiene work will continue to be unsatisfactorily done. In order to train such individuals we must demand an increasing amount of preliminary medical education, particularly specialization in the field of pediatrics, and several years of special study including practical experience in the field.

#### SUMMARY

Instruction in child hygiene may be obtained at the present time under 3 auspices. First, in postgraduate work in pediatrics conducted by various medical schools. These courses do not deal with child hygiene as such, but a considerable amount of valuable information concerning well children and normal growth and development is presented. For further details one should consult the report on pediatric education prepared by Dr. Borden Veeder for the White House Conference on Child Health and Protection.

Second, in connection with undergraduate and postgraduate instruction in certain special schools in various universities. These courses are also fragmentary, considering various aspects of the child hygiene problem but not attempting in any way to cover the entire field of child health. The better organized of these courses are as follows:

At Yale courses on infant welfare, school hygiene, and municipal health department activity.

At the University of Toronto, a course in school hygiene.

At Columbia University, courses in preventive medicine and public health administration, school health inspection, and school health supervision.

At the University of Minnesota, a course in child welfare.

At the University of Iowa, courses on child development, nutrition, and child psychology.

At the Massachusetts Institute of Technology and Boston University, courses on health education.

Third, fairly complete but somewhat superficial courses in connection with schools of public health at Johns Hopkins and Harvard.

---

## Good Eyesight in Industry

IN my organization, during 8 years, approximately 11,000 pairs of eyes were examined at the Pullman Car Works, with 25,843 separate visits. Of these, 42 per cent achieved normal vision (some had normal vision while others required glasses to make them normal). Fair vision was obtained in 37 per cent with or without glasses. This makes 79 per cent with good or fair vision in both eyes, leaving 21 per cent with poor or bad vision in one eye or both, that glasses could not help. Of this 21 per cent, 0.6 per cent were one-eyed men.

This does not mean that 21 per cent had at least one bad eye since some of the examinations were preemployment and were rejected, others were employees of interlocking companies and others were pensioners.

Good eyesight obviously reduces the employer's compensation payroll and also the salvage bill. This far overshadows the cost of medical care and the cost of protective goggles—not to speak of the humanitarian phase of the question.

The eye requirements at selected positions in an industrial plant are summarized in a table from which the following excerpts are taken:

*Without glasses*, crane operators should have a vision of 20/30 or better while transportation employees should have 20/20 in addition to color tests. Other employees involving machinery, woodworking, welding, etc., should have 20/40. *With glasses*, transportation employees should have 20/20, transfer table employees 20/20 one eye, 20/30 the other, while all the other groups mentioned should have 20/30.—

Herman P. Davidson, *Sight-Saving Rev.*, 1, 4: 38-41 (Dec.), 1931. E.R.H.

# Food Poisoning Due to Toxic Substances Formed by Strains of the Cloacae-Aerogenes Group\*

RUTH GILBERT, M.D., F.A.P.H.A., MARION B. COLEMAN  
AND ALICE B. LAVIANO

*Division of Laboratories and Research, New York State  
Department of Health, Albany, N. Y.*

AN increasing variety of bacterial species including *B. cloacae*, *B. proteus*, and staphylococci, is being found to incite gastrointestinal disturbances following the consumption of food containing these microorganisms or their toxic products, as is exemplified by the work of Buchanan and Megrail,<sup>1</sup> Bengston,<sup>2</sup> Baerthlein,<sup>3</sup> Ilsley,<sup>4</sup> Dack and his coworkers,<sup>5</sup> Jordan,<sup>6</sup> Ramsey and Tracy,<sup>7</sup> and Barber.<sup>8</sup>

Early in October, 1930, an outbreak of gastroenteritis attributed to cream-filled pastry occurred, the outstanding epidemiological features of which were described in *Public Health News* of New Jersey<sup>9</sup> and *Health News* of New York.<sup>10</sup> At least 125 cases were reported to have developed on 2 successive days in an area approximately 20 miles square, those occurring on the first day being confined chiefly to the southern part of the district. The symptoms were said to have been manifested in every case within a few hours after the eating of either cream puffs or chocolate éclairs manufactured by a wholesale bakery. A few of those who ate the pastry noticed a metallic or gaseous taste, but most of them did not report any unpleasant taste or odor. The illness was characterized by violent and prolonged nausea and vomiting, followed by a profuse diarrhea and, in some instances, cramps affecting the leg muscles. No rise in temperature was noted. The symptoms generally subsided in from 4 to 10 hours. The description of the cases occurring on the second day indicated that they were markedly more severe than those of the first. In fact, the administration of morphine was required in many instances.

The bakery was visited by a member of the laboratory staff on the day following the outbreak. It was in a concrete building which

\* Read before the Laboratory Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 17, 1931.

appeared to be so constructed that few rats and mice could gain entrance. Traps, but no poisons, were used. The work rooms and all utensils were scrupulously clean, and containers had properly fitting covers. The method of preparing the cream filling was as follows: Eggs, cornstarch, and milk powder were mixed, poured into a sugar solution previously heated, and cooked with constant stirring until thick. The material was heated to approximately 100° C., but was kept at this temperature for only a very short time, then left in a covered, tin mixing-bowl, at room temperature, for 4 or 5 hours before the shells were filled. The pastries were kept in a refrigerator overnight and distributed by automobile truck on the following morning.

The eggs were obtained from a firm which handles "cracked eggs," which are removed from the shells, put in tin cans, and distributed to bakeries, restaurants, etc. The eggs used on the second day were said to have been taken from a half-filled can which had been in the refrigerator overnight. None of this lot was available for examination and the can in which they were shipped had been discarded.

Six specimens were secured of cream puffs and chocolate éclairs, some of which were portions of those eaten by individuals who were ill. Unfortunately, only those distributed on the second day were available. Fecal specimens were obtained from 7 patients. Examination of the filling failed to show evidence of chemical poisons. None of the species generally associated with enteric disease were found in any of the specimens. *Staphylococcus aureus* was present in large numbers in the cream filling of the 6 pastry specimens and was also found in 2 fecal specimens.

In a study of a representative strain of these organisms isolated from the filling, a monkey was fed with 5 c.c. of a 48-hour culture grown in medium containing ingredients similar to those used in the pastry filling; a guinea pig and a mouse were inoculated intraperitoneally with 2 c.c. and 1 c.c. respectively of a filtrate from it; a rabbit was inoculated intravenously with 3 c.c. of this filtrate, and another with the same amount of the filtrate from a broth culture. None of the animals showed any evidence of illness.

From 5 fecal specimens and from the filling of 5 cream puffs or éclairs large numbers of nonmotile, Gram-negative, encapsulated bacilli were isolated, the growth products of which proved toxic for certain animals. The biochemical reactions indicate that the strain belongs to the cloacae-aerogenes group, although it does not correspond

exactly to any species for which a description could be found. With one possible exception, no evidence of motility has been demonstrated. Two stained films of one culture, however, have shown monotrichous

PLATE I—ORGANISMS SHOWING CAPSULES AND MONOTRICHOUS FLAGELLA.  $\times 1,000$  DIAMETERS.

flagella (see plate I). Dextrose and lactose are fermented, at least three times as much gas being produced in the former and about twice as much in the latter as is formed by *B. coli*. Saccharose, maltose, mannitol, glycerol, inositol, and starch are also fermented, while dulcitol and adonitol are not. The majority of the strains liquefy gelatin very slowly, requiring from 8 to 14 weeks at from  $35^{\circ}$  to  $37^{\circ}$  C. Litmus milk is acidified and coagulated; indol is not produced. Acetyl-methyl-carbinol can be demonstrated in dextrose broth (Voges-Proskauer positive) after 24 and 48 hours' incubation, but not after a longer period; the reversion of reaction in 0.5 per cent dextrose-phosphate-peptone solution (methyl-red negative) is rapid, occurring within 24 hours. As our experience would indicate that this group of organisms is not frequently found, in considerable numbers at least, in human feces, the presence of the particular strain described in 5 of 7 of the stools from persons ill following the eating of the cream puffs is of significance.

Antiserum produced with 1 strain (No. 328) isolated from the cream-puff filling agglutinates to its full titer the other 9 strains. With one exception, no appreciable reaction with other available strains of the cloacae-aerogenes group was obtained. A culture isolated in the branch laboratory in New York City from cream-pie

filling, to which were attributed 2 cases of food poisoning in 1 family, was agglutinated to one-half the titer of the antiserum. This culture is motile and differs slightly from No. 328 in biochemical reactions. It liquefies gelatin rapidly and ferments dulcitol but fails to ferment glycerol and starch; acetyl-methyl-carbinol is demonstrable in dextrose broth for 7 days. Its toxicity has not as yet been determined.

A medium similar to the pastry filling, as well as beef-infusion broth, was used for studying the toxigenicity of strain No. 328. The custard medium was prepared according to the following formula:

CUSTARD MEDIUM

225 c.c.	Milk
100 c.c.	Water
53 gm.	Saccharose
15 gm.	Cornstarch
0.5 gm.	Sodium chloride
1	Egg
3 c.c.	Vanilla extract

Place the milk and 80 c.c. of water in a double boiler and heat until a scum forms. Mix the sugar, cornstarch, and sodium chloride with the remainder of the water and add the well beaten egg. Combine with the hot milk and cook slowly until thick. Distribute in flasks or tubes and sterilize in an autoclave at 115° C. for 20 minutes.

Unless otherwise stated, all cultures of No. 328 used for feeding or inoculation were incubated for 24 hours, while filtrates tested for toxicity were obtained from 48-hour cultures. No evidence of toxicity for mice or guinea pigs was observed following the feeding of custard-medium culture or subcutaneous inoculation with broth culture. Intraperitoneal inoculation with 1 c.c. of broth culture was followed in mice by diarrhea within 1 hour, and by death of both mice and guinea pigs within 24 hours; animals of both species remained alive and well after similar inoculation with culture filtrates.

A monkey was fed approximately 5 c.c. of a 48-hour culture in custard medium, subsequent to which diarrhea, but no other symptoms of illness, was observed. Two hens fed custard-medium culture and 1 inoculated intravenously with broth culture developed diarrhea within from  $\frac{1}{2}$  to 3 and 6 hours, respectively. Rabbits inoculated intravenously with from 0.1 c.c. to 5 c.c. or fed with from 2 c.c. to 5 c.c. of filtrate from the custard-medium culture developed diarrhea within from 15 minutes to 6 hours, but usually recovered.

Similar results were obtained with this material after it had been heated to 100° C. Broth-culture filtrates caused diarrhea when given intravenously, but no symptoms were observed after feeding such

filtrates to rabbits. A kitten fed about 20 c.c. of a 24-hour culture grown in the custard medium showed no ill effects.

The epidemiology clearly points to cream puffs and chocolate éclairs as the source of intoxication. Since the cream filling was said to have been prepared each morning, a common vector is indicated. All the ingredients except the eggs and water were dry and it was understood that portions of material from the same lots were used both before and after the outbreak.

The data suggest, therefore, that the etiological agent might have been introduced by means of the eggs, which may have been contaminated from the shells, the persons removing them from the shells, or some other source. Although the mixture was cooked after the eggs were added, it is conceivable that a portion of the custard, especially that adherent to the kettle near the top, may not have been heated sufficiently to destroy the bacteria. Furthermore, if the toxin of the organisms of the *cloacae-aerogenes* group described had already been formed, it might not have been rendered inactive by the method of cooking employed.

While the pastry was said to have been kept in the refrigerator overnight, ample time elapsed for incubation of the bacteria during the 4 or 5 hours the cream filling was left at room temperature before the pastry shells were filled, and again the following day when the finished products were being distributed by truck, the temperature being unusually high for that season.

The highest standards of cleanliness cannot prevent contamination of food from dust, utensils, egg shells, and other similar sources which are known to harbor numerous so-called saprophytic microorganisms. Certain of these bacteria, in themselves innocuous, under favorable conditions produce substances which, if ingested, may prove markedly toxic. The frequent reports of outbreaks of food poisoning following the consumption of pastries containing cream-custard filling suggest that this material—possibly owing to the egg content—furnishes an excellent medium for the development of harmful bacterial products. Although the subjection of these foods to temperatures necessary for sterilization is not practicable, the production of toxic substances can be averted by continuous refrigeration during the brief period before distribution to the consumer.

The handling and refrigeration of "cracked eggs" may need more careful supervision. It seems important that steps be taken to control the preparation and distribution of all cream-custard food products, as well as to disseminate information to the public to insure necessary precautions on the part of the consumer.

## Dental Research

AN important symposium on the cause and nature of tooth decay was held June 23 in Pittsburgh, at the Frick Training School, under the auspices of the Pittsburgh Section of the International Association for Dental Research. The main papers were presented by Dr. H. E. Friesell, Dean of the University of Pittsburgh School of Dentistry, and Dr. J. J. Enright, a research specialist of Mellon Institute. These contributions gave the first complete account of the results of the comprehensive scientific investigation of tooth decay or dental caries that has been in progress at the University of Pittsburgh during the past nine years.

In the reading and discussion of the papers by Drs. Friesell and Enright it was brought out that the new additions to dental knowledge resulting from this broad investigation were as follows: first, the determination of the effects of acids on tooth enamel under natural conditions; secondly, the discovery of the relation of the calcium phosphate content of the saliva to tooth decay; thirdly, the identification of the lactobacilli that cause tooth decay; and, fourthly, the description, in a preliminary way, of the results of a clinical study that demonstrated that an oral prophylactic program efficient in reducing the massive lactobacilli infection of the dental zone decreased by 66 per cent the amount of new tooth decay developing in a year.

# Inter-Chamber Health Conservation Contest \*

CHARLES W. GOLD

*Chairman of the United States Chamber of Commerce Health Conservation  
Contest Committee*

THIS closes the third year of the Inter-Chamber Health Conservation Contest which has been fostered and conserved by the Insurance Department of the United States Chamber of Commerce. Through the generosity of insurance companies it has been possible for representatives of the American Public Health Association to visit cities entered in the contest and discuss their community health programs. When the contest was started in 1929 it was announced that the purposes were two-fold: First, to acquaint citizens, particularly business men, with the work of their local health agency, and their communities' local health problems, with a view to bringing about improvements which would mean economic gain, for certainly community security and community comfort are real assets. Second, to provide an additional means for reducing preventable illness and untimely death. Each community must be measured eventually by the intelligent effort which it makes for a solution of these problems. While results of the contest with respect to the second purpose cannot yet be fully measured, yet insurance statistics show that there is an improvement in mortality from preventable diseases, and this of course is a factor in carrying out the first objective.

Among the many general collateral benefits resulting from the contest we find first, dissemination of general information on public health; second, the coördination of the work of local health agencies, thereby tending to eliminate overlapping activities and to stimulate concerted efforts on local health needs; and third, the keeping of records in better form and so that they are comparable with those of other communities. In addition to those general results there are also in many instances specific local accomplishments conferring immediate and lasting benefits on the community. While the Health Contest is not claimed to have been the only factor in making such accomplish-

\* Presentation of Awards to the winning cities in the 1930 Health Conservation Contest at the Annual Meeting of the Chamber of Commerce of the United States at San Francisco, Calif., May 20, 1932.

ments possible, it has provided the occasion for doing those things which previously were being considered and which lacked the influence and propelling force supplied by the Chamber of Commerce Health Committee.

Leading examples of recent improvements in public health, in the effectuation of which numerous local chambers of commerce have had a definite part, include: measures for improvement of milk supply; initiation of diphtheria immunization programs; periodic health examinations; surveys of public health activities; sanitary improvements; and medical examination of school children. Among other definite activities are those bringing about better coöperation between local practising physicians and health agencies, the establishment of many health services to include rural and urban districts. Such specific advances as new sanitary codes, movements for malaria control, new tuberculosis sanatoriums, etc., are but yard-sticks by which to measure the general advance.

The illustrations just mentioned indicate that chambers of commerce recognize the improvement of their communities' public health as a matter of interest to citizens. Let it be understood that the chambers in no way are interested in usurping the activities being carried on by their local health agencies. They are acting as coöperating bodies which make possible definite accomplishments which would be difficult or well nigh impossible for the local health agencies if left alone. The health activities being carried on by local chambers as they participate in the Inter-Chamber Health Conservation Contest are sometimes hard to measure in a tangible way; nevertheless, business and industry are coming to recognize more and more the fact that improvements in public health do produce economic gains.

The 1931 Contest has been the most successful of any of the contests during the 3 years of their existence. An increase in 1931 of more than 27 per cent in enrollment over that for 1930, 265 cities located in 45 states, the District of Columbia, and Hawaii, being represented, shows real progress. It is noteworthy that, even though the requirements in 1931 for a full score were made considerably more exacting, more than 70 per cent of the cities in the Contest for both 1930 and 1931 made higher scores for the latter than for the former year—and if allowance is made for the higher requirements there would be more than 90 per cent of these cities with higher scores in 1931.

The Board of Judges in rating the various cities in the 1931 Contest for the 6 population groups named a winning city, with 5 others

in each group being given honorable mention. An exception is that in Group V, 6 honor cities were named. These 37 award cities were located in all parts of the country. The State of New York led with a total of 6, California and New Jersey coming next in order with 5 each, followed by Wisconsin with 4, and Illinois with 2 winning cities.

As a Director of Insurance of your National Chamber of Commerce and as chairman of your departmental committee of insurance, may I be permitted to urge that each local chamber of commerce take a special interest in this health conservation work. We are asking for a closer tie-up between the city and county health departments and the local chamber, the idea being that this Inter-Chamber Health Contest will bring a standardization of requirements as to health facilities.

It is now a pleasure to give you the names of winning and honor cities in each of the population groups and, to the winner in each group, present a plaque in recognition of its activities and achievements in health conservation. In passing, may I, however, state that among those cities designated as leaders, in many instances the difference in score was very slight, as was also the margin of score for some of the honor cities over those standing immediately next to them. To the honor cities engraved certificates have been sent.

*In population Group I*—cities more than 500,000 population—the following, according to alphabetical order, are the award cities:

Baltimore, Md.	Philadelphia, Pa.
Detroit, Mich.	Pittsburgh, Pa.
Milwaukee, Wis.	St. Louis, Mo.

Milwaukee, which won in 1929, is again the winner in 1931.

*Of Group II cities*—between 250,000 and 500,000 population—the following are award cities:

Cincinnati, O.	Newark, N. J.
Kansas City, Mo.	Rochester, N. Y.
Minneapolis, Minn.	Toledo, O.

Rochester, for the past 2 years has been an honor city and now it stands first.

*Cities in Group III*—100,000 to 250,000 population—showed the following award cities:

Grand Rapids, Mich.	Syracuse, N. Y.
Hartford, Conn.	Utica, N. Y.
New Haven, Conn.	Yonkers, N. Y.

Group III is the only group in which a city has been a winner for 2 successive years. New Haven stands in first place.

*Award cities in Group IV*—50,000 to 100,000 population—are as follows:

East Orange, N. J.  
Evanston, Ill.  
Harrisburg, Pa.

Kenosha, Wis.  
Pasadena, Calif.  
Racine, Wis.

In this group we find Evanston one of the 2 winning cities from the State of Illinois, as the leader.

*Group V*—cities between 20,000 and 50,000 population—showed the following in the award group:

Alhambra, Calif.  
Brookline, Mass.  
Maplewood, N. J.  
Newburgh, N. Y.

Orange, N. J.  
Watertown, N. Y.  
West Orange, N. J.

Brookline, Mass., participated in the 1931 Health Contest for the first time and was the winning city in its group.

*Group VI cities* in the Contest included all those under 20,000 population. The award cities were as follows:

Chestertown, Md.  
La Salle, Ill.  
Lodi, Calif.

Monrovia, Calif.  
Palo Alto, Calif.  
Shorewood, Wis.

In this group, another Illinois city, La Salle, is the first award city. La Salle during the first 2 years of the Contest was also an honor city. Efforts each year have rewarded it with first place in 1931.

## THE WESTERN BRANCH MEETING

THE third annual meeting of the Western Branch of the American Public Health Association was held June 9, 10 and 11, with headquarters at the Brown Palace Hotel, Denver, Colo. The meeting was well attended, with a registration of 230. There was an excellent selection of papers on practically every phase of public health. Naturally many of these referred to conditions which are particularly prominent in our western states, and along the Pacific Coast, though all of them were interesting from the public health standpoint, and many of them had a country-wide bearing. There is no question that the growth of the Western Branch in the three years of its existence has been phenomenal, and that it is playing a dominant part in the direction of public health opinion in the West as well as its expression in print and its carrying out in practice.

There was but one observable drawback to the meeting; namely, the absence of men from the East, a number of whom were on the program, but prevented from coming for one reason or another, largely on account of the depression, including the expense of travel and absence from office work.

A feature of the meeting was a garden party given by that dean of tuberculosis workers, Dr. Henry Sewall, and his charming wife. All

those in attendance at the Western Branch meeting as well as those who had attended the meeting of the National Tuberculosis Association in Colorado Springs, which immediately preceded, were invited, and many enjoyed the privilege of meeting Dr. and Mrs. Sewall as well as partaking of their gracious hospitality. Both Colorado Springs and Denver were at their best. There was still a good deal of snow on the mountains, and nature did all she could to make things entrancing.

The meeting of the National Tuberculosis Association was unexpectedly well attended, the registration being so large (550) that the programs ran short. Again, however, there was a notable absence of members and delegates from the eastern states. On Tuesday, June 7, a joint meeting with the Colorado State Society was held at the Broadmore Hotel and a dinner, attended by more than 300, was given in honor of the 50th Anniversary of the discovery of the tubercle bacillus by Robert Koch. Both meetings were most enjoyable. The people in both cities were hospitable to the last degree, and it is safe to say that all who had the good fortune to be present carried away delightful memories in addition to the scientific knowledge acquired from the reading of papers.

#### CHARLES V. CHAPIN, M.D.

THE resignation of Dr. Charles V. Chapin as Health Officer of the City of Providence, R. I., after 48 years of service, calls for more than passing notice. With no disrespect to anyone, it may be said without any fear of contradiction that Dr. Chapin has occupied for many years the position of Dean of City Health Officers.

During his service he introduced many new practices, the most important perhaps being the doing away with terminal disinfection. After a series of careful experiments, with and without terminal disinfection, he decided that it was an expense which was not justified. Since that time many cities have followed his lead. While he was not a prolific writer, his book, *The Sources and Modes of Infection*, has been for many years a standard.

Dr. Chapin could have had any honor which he desired, but with a sincere and unusual modesty he combined a rather frail physical make-up, so that many were declined. He could have been President of the American Public Health Association at any time he cared to signify his willingness to accept the honor. Finally in 1927 he was persuaded to do so, and the Association felt itself honored in having

him serve. He was the first recipient of the Sedgwick Memorial Medal and no committee ever made a selection which received more unanimous approval than this. One of the last honors done him was a resolution adopted in December, 1931, just when he was about to relinquish his office, changing the name of the Providence City Hospital to the Charles V. Chapin Hospital.

It is not flattery to make the statement that there is no member of our Association who for so many years has retained the admiration, respect, and affection of its membership. We wish him all happiness in his quiet home with Mrs. Chapin who, as all of us remember, came with him regularly to the meetings of the Association which he was able to attend.

---

## THE FOLGER SHAKESPEARE LIBRARY

CURTIS HODGES

*Executive Director, Greater National Capital Committee,  
Washington, D. C.*

A NEW attraction in Washington, and one that is drawing literally thousands of visitors each week, is the Folger Shakespeare Library, unexcelled for the architectural beauty of its build-

ing and its rare collection of Shakespeareana. It is a 10-million-dollar institution made possible by the beneficence of Henry Clay Folger, prominent business executive who devoted large

*Folger Shakespeare Library, Washington, D. C.*

sums of money and many years of personal effort to its perfection.

Through more than five decades, Mr. Folger day by day and month by month accumulated the most valuable and use-

gant praise. The words of Walter Prichard Eaton, essayist and critic, pronounced on the day of the dedication are peculiarly apt:

"All scholars will rejoice that the Folger collection is made available and it should be a matter of pride to all of us that the library which houses it is in the National Capital, marking one more step in the development of that city, not only toward a place of civic beauty but of intellectual wealth."

The Folger Library is situated on East Capitol Street between Second and Third Streets, the site having been selected personally by Mr. and Mrs. Folger. To build the library there, it was necessary to raze 14 houses, and the procedure of obtaining titles to these buildings required 9 years. Alexander B. Trowbridge was the consulting and supervising architect and Paul P. Cret was the architect.

The building is of glistening white marble and is noted for its simplicity in design. In size, it is not comparable to the other large buildings of Washington, but it has a distinctive charm.

"I did think of placing the Shakespeare Library at Stratford near the bones of the great man himself but I finally concluded I would give it to Washington; for I am an American." These were the words of Mr. Folger.

And as a result of Mr. Folger's imagination, his ability, and his loyal American spirit, the people of this nation have a new shrine in their national city.

*Entrance to Exhibition Hall  
Folger Shakespeare Library*

ful mementos of Shakespeare to be found on both sides of the world, and this vast collection is now housed in the new snow-white building directly across from the Congressional Library. This noble structure in its carefully cultivated lawn and with its marvelous and dignified shrubbery, takes a high place among the worthwhile sights of Washington.

Its dedication on Saturday, April 23, was attended by dignitaries, savants, and leading men from all walks of life, and all gave the new institution extrava-

## LETTER FROM GREAT BRITAIN

### A PIONEER IN FACTORY HYGIENE

BY the death of Sir Thomas Legge, preventive medicine has lost one who in his day was responsible for many contributions of real value, in the realm of industrial hygiene especially.

During the years he acted as Senior Medical Inspector of Factories at the Home Office, a position he succeeded to on the retirement of Sir Arthur Whitelegge, he sought in every way possible to secure healthy conditions for the industrial worker. Particularly he sought to have introduced every available measure that research and experience showed to be essential as a protection to health and a preventive of injury or disease. In these regards he endeavored to promote coöperation between all parties concerned, including employers and employees, and he was all for placing the main control in the hands of the Factory Department.

Actually he had little use for local health authorities, and one of his strongest convictions was that the less the medical officer of health was given to do with factories and the health of the factory worker the better it would be for everybody.

The absence of direct relation between the Factory Department and the Ministry of Health was an arrangement of which he entirely approved. He rarely missed an opportunity, either before or after his retirement from office, of saying so. Nor did he hesitate to assert that industrial hygiene and trade diseases and poisonings were matters so definitely for the specialist that no ordinary medical practitioner should be allowed to give even the most elementary addresses upon them to a

popular audience. This rather uncompromising attitude of mind was typical of the man and was responsible for his resignation of his post of Senior Medical Inspector, the ground being that certain regulations issued by the Home Office with regard to the prohibition of the use of white lead for the internal painting of buildings did not go so far as he believed they should, having regard to the recommendations of the 1921 International Convention at Geneva.

After his retirement Sir Thomas Legge continued to take a great interest in industrial affairs, associating himself with the work of the Trades Union Congress, the Industrial Health Education Society and other bodies.

He was extremely keen on teaching and made himself responsible for some part of the instruction given to students on industrial hygiene and diseases at the London School of Hygiene. This work will now be carried on by Dr. Middleton of the Factory Department, who, among other matters, has devoted a great deal of time and study to the subject of pulmonary silicosis.

### CUTS IN THE HEALTH SERVICES

UP to the present, as a result of the economic situation, the amount of interference with health activities, national and local, has been comparatively slight. Indications that this state of affairs is not likely to continue appear from time to time, however, in the public statements of members of the Government and otherwise.

The Minister of Health himself rather unexpectedly, since it is not so long ago that he pointed with some pride to the

smallness of the cuts in health expenditure, recently made a strong appeal to all local authorities to adopt as a policy the postponing of all forms of capital expenditure not essential for the public health or in relation to any other question of general public necessity. Giving it as his opinion that things had been placed on lines that would lead to prosperity, he still thought that the proper course was to restrain public expenditure wherever with safety it could be restrained, in order to increase the funds available under the control of private enterprise for the restoration and expansion of the essential industries of the country.

The view that there are vast possibilities of saving by way of cuts in social services appears to be widely held, particularly by the newer and younger members of Parliament. The big changes that took place in the personnel of Parliament following the recent election have been responsible for a number of happenings that must have caused distress and annoyance to persons accustomed to a more or less uniform procedure no matter what party happened to be in power.

So many of the new people are young and in a hurry that, without troubling to learn or thinking of consequences, they dash at things and make demands that to the old fashioned appear outrageous. More especially many of the newer and younger people are a little inclined to regard Parliament and the central governing body as a great deal more powerful and superior to the local bodies than is actually the case. Public health, for example, always regarded as much more of a local than a central concern, has been more definitely so regarded since the passing of the Local Government Act, 1929; and, even if it could, Parliament directly or through the government departments interferes very little. This many of the newcomers

to Parliament apparently do not know. If they did they probably would not, as some have done, talk about restrictions upon the freedom of action of local authorities in carrying out statutory duties, and thus run the risk of rousing the resentment of these authorities, even in the interests of what they describe as "public economy."

Doubtless savings could be effected if duties were limited or restrictions were imposed; but so they could if restrictions were removed in certain cases. Annually, for example, large sums must be spent by local authorities on housing and slum clearance, and if something could be done to reduce expenditure in this direction the public purse might, though the public health might not, benefit.

#### LONDON'S WATER IN 1931

THIS is the season when annual reports begin to make their appearance. One of the most interesting just come to hand is that of Sir Alexander Houston, Director of Water Examination to the Metropolitan Water Board.

Issued primarily to give the results of the chemical and bacteriological examination of the London waters for the previous 12 months, during recent years, at any rate, these reports of Houston's have provided him with an opportunity of singing songs in praise of the beauty of the rivers Thames and Lee from which the metropolis obtains the bulk of her water supply. In general also the descriptions are illustrated with most attractive photographs and extracts from the poetry and prose writing lovers of the river.

Even in the more technical portions of his report Sir Alexander is unable to resist digression, and a reference to a search for the *Bacillus typhosus* in some particular sample is as likely as not to lead him into a discussion of and an ex-

pression of view upon some historic epidemic of enteric.

The report for the year 1931, although "owing to financial considerations" its scope had to be greatly curtailed, presents all the familiar features, the practical and technical being lightened by much talk of the County of Essex, and a description of a journey through Epping Forest to Epping, where an outbreak of paratyphoid fever occurred in the early part of 1931. Having found that this was due to contaminated milk and not to the water for which he is responsible, Sir Alexander devotes a number of pages to a discussion of the advantages of the

pasteurization process as applied to milk. Also he expresses astonishment at the lowness of the bacterial standards prescribed in the case of milk, and as regards purity compares that liquid most unfavorably with that with which he himself is more intimately concerned.

A report of water examinations could, I imagine, be an immensely dull production. In the hands of Sir Alexander Houston it becomes, both to the expert and the general reader, worth the price—approximately \$2.00—at which it is offered.

CHARLES PORTER, M.D.

London

## ASSOCIATION NEWS

*Sixty-first Annual Meeting of the A.P.H.A.  
Washington, D. C., October 24-27, 1932  
Headquarters, Willard Hotel*

### ANNUAL MEETING INFORMATION

#### REDUCED RAILROAD FARES

**R**EDUCED railroad fares on the Identification Certificate Plan have been authorized by the several Passenger Associations in the United States and Canada, which will entitle all members and dependent members of their families to a special rate of a fare and one-half for the round trip to Washington.

Under this plan an Identification Certificate *must be presented* to the ticket agent when purchasing tickets. (One will be mailed to every member of the Association about September 10.)

This is the ticket agent's authority to issue to delegates and dependent members of their families a round-trip ticket to Washington at the reduced rate. All return tickets must be validated, before leaving Washington, at the regular railroad ticket office.

It is suggested that all members consult their local ticket agents in regard to dates of sale as they vary according to distance from Washington.

The final return limit is 30 days in addition to date of sale. Delegates may travel to and from Washington via the same route or via diverse routes, as they prefer, without additional cost.

## RAILROAD RATES FROM VARIOUS CENTERS TO WASHINGTON, D. C.

	Regular Rate One-Way	Special Rate Round Trip <i>Fare-and-a-Half</i> Basis		Lower Berth One-Way	Upper Berth One-Way

## COMMITTEE ON TRAINING AND PERSONNEL

The Committee on Training and Personnel, with the approval of the Executive Board, has adopted the following general plan for the registration of Health Officers. It is arranged:

1. That during the year 1932 the American Public Health Association register all full-time executive officers of health departments who seek registration according to the plan organized by the Committee on Training and Personnel.

2. That the names and data concerning these individuals be published in alphabetical order in a directory.

3. That there be included for registration persons who served as full-time executive officers for not less than 2 years and who have not been out of the public health field for more than 2 years and who seek registration according to the plan organized by the Committee on Training and Personnel.

4. That some plan be devised whereby individuals may be registered in the future

through an examination given under suitable auspices whereby they can demonstrate a satisfactory knowledge in specified subjects.

5. That the Committee on Training and Personnel and the executive office undertake an educational program to secure support from public organizations for the program of the Committee on Training and Personnel looking to the improvement of tenure and training for public health workers.

6. That the sub-committee uphold and approve the general principle of legal licensing of executive officers in public health.

Registration is not restricted to members of the Association. However, as in other professional directories (like the A.M.A.) names of members in the Association will be printed in large type.

Registration was begun several days

ago when blanks were sent to 772 full-time state, county, and city health officers. We are, however, finding it difficult to reach those who have served as full-time executive officers for not less than 2 years and who have not been out of the public health field for more than 2 years or are, at the present time, engaged in some other phase of public health work. If you belong to either of these groups and wish to register will you kindly secure a registration blank from the Committee on Training and Personnel, American Public Health Association, 450 Seventh Avenue, New York, N. Y.

## NEW MEMBERS

*The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.*

### *Health Officers Section*

H. M. Batson, M.D., Cadiz, Ky., Director,  
Trigg County Health Dept.  
William D. Cagle, M.D., Lebanon, Tenn.,  
Director, Wilson County Health Unit  
W. R. Culbertson, M.D., Norton, Va., Wise  
County Health Officer  
John B. Derrickson, M.D., Georgetown, Del.,  
Unit Health Director  
Charles H. Eller, M.D., Box 2, Los Lunas,  
N. M., Valencia County Health Officer  
Joseph J. Gerkins, M.D., Pikeville, Ky.,  
Director, Pike County Health Unit  
Thomas N. Horan, M.D., Bloomfield Hills,  
Mich., Health Officer  
Arden J. Butler, M.D., Covington, Tenn., Tip-  
ton County Health Director  
I. N. King, M.D., Prince Frederick, Md.,  
Calvert County Health Officer  
Reuben H. Leavitt, M.D., Carson, N. D.,  
County Health Officer  
Dr. James M. Parrott, Raleigh, N. C., State  
Health Officer  
Guy Post, M.D., White Cloud, Mich., Director,  
Newaygo District Health Unit  
W. H. Y. Smith, M.D., Perry, Fla., Director,  
Taylor County Health Unit  
George H. Spelman, Mandan, N. D., City  
Health Commissioner  
J. Syrnington, M.D., Carthage, N. C., Moore  
County Health Officer

H. M. Wallace, M.D., Staunton, Va., Augusta  
County Health Dept.

### *Laboratory Section*

Victor W. Bergstrom, M.D., 21 Park Ave.,  
Binghamton, N. Y., Director, Kilmer  
Pathological Laboratory

### *Public Health Engineering Section*

Elmore E. Butterfield, M.D., 70-04 Dartmouth  
St., Forest Hills, N. Y., Consulting Chemist  
Harry E. Jordan, 113 Monument Circle,  
Indianapolis, Ind., Filtration Engineer,  
Indianapolis Water Company  
Dick C. Thompson, Nashville, Tenn., Davidson  
County Sanitary Engineer  
J. Summie Whitener, P. O. Box 5171, Raleigh,  
N. C., Assoc. Professor of Sanitary Engineer-  
ing, North Carolina State College

### *Food and Nutrition Section*

Julius H. Comroe, 353 S. George St., York,  
Pa. (Assoc.)

### *Child Hygiene Section*

William H. Griffin, D.M.D., 1108 City Hall  
Annex, Boston, Mass., Dental Director,  
Dept. of Health  
Mabel E. Rugen, Ph.D., Barbour Gymnasium,  
Ann Arbor, Mich., Instructor of College  
Classes

James J. Siragusa, M.D., 261 Hanover St., Boston, Mass., Medical Inspector, Dept. of Health

Luigi P. Verde, 699 Adams St., Dorchester, Mass., Medical Inspector, Boston Dept. of Health

## Public Health Education Section

Rexwald Brown, M.D., 1421 State St., Santa Barbara, Calif., Director, Santa Barbara Clinic

Alexander M. Carr, Washington Square Building, Royal Oak, Mich., Pediatrician

Marcos Fernan-Nunez, M.D., 1848 N. 4th St., Milwaukee, Wis., Director, Dept. of Pathology and Bacteriology, Marquette University Medical School

Earl E. Kleinschmidt, M.D., 119 N. Thayer St., Ann Arbor, Mich., Instructor in Public Health and Hygiene, University of Michigan

Elizabeth P. Robinson, University Health Service, Ann Arbor, Mich., Supervising Nurse and Instructor of Hygiene and Public Health

Dr. Georg Seiring, Deutsches Hygiene Museum, Dresden, Germany (Assoc.)

Robert E. Wodehouse, M.D., 304 Plaza Bldg., Ottawa, Ont., Canada, Executive Secretary, Canadian Tuberculosis Association

## Public Health Nursing Section

Maud A. Conkling, R.N., Yorktown Heights, N. Y., School Nurse

Bertha Knipfer, 614 Robert E. Lee Apt., Nashville, Tenn., Davidson County Field Nurse

Bessie H. Morse, Covington, Tenn., Tipton County Nurse

Gladys M. Piper, R.N., 416 Carolina Ave., Bristol, Tenn., Chief Nurse, Sullivan County Health Dept.

Margaret B. S. Schinz, R.N., 1144 Henry Clay St., Milwaukee, Wis., Village Nurse, Whitefish Bay

Sarah Smith, R.N., Manderson, S. D., Nurse, Indian Service

Beulah White, R.N., Ashdown, Ark., Public Health Nurse

Louise Zorn, R.N., Court House, Kelso, Wash., Cowlitz County Nurse

## Epidemiology Section

Harlin L. Wynns, M.D., 358 State Building, San Francisco, Calif., Junior Epidemiologist, State Dept. of Health

## Unaffiliated

William D. Rankin, M.D., 51 E. 50 St., New York, N. Y. (Assoc.)

.....(Cut off on this line and mail to the hotel of your choice).....

## HOTEL RESERVATION BLANK FOR WASHINGTON MEETING

### AMERICAN PUBLIC HEALTH ASSOCIATION

450 SEVENTH AVENUE, NEW YORK, N. Y.

OCTOBER 24-27, 1932

To .....  
(Name of Hotel)

Please reserve for me.....rooms for.....persons  
for the A. P. H. A. Meeting. (Cross [X] is placed after my preference.)

Single room.....Double room.....

Maximum rate per day for room \$.....Minimum rate per day for room \$.....

I expect to arrive..... If date of arrival is changed I will notify  
you at least 24 hours in advance.

Please acknowledge this reservation.

Name .....

Street address.....

City..... State.....

# PUBLIC HEALTH ADMINISTRATION

Racine, Wis.—The new quarters of the health department provide adequate space and proper facilities for carrying on a well rounded health program. Community Health Day, with a special demonstration, marked the opening of these new quarters.

A general health education program has been developed. A monthly bulletin, special health lectures, newspaper and magazine articles, and special folders on smallpox vaccination and diphtheria immunization were utilized. A unique feature was the development of dramatic health episodes broadcast three times weekly over station WRJN.

The crude death rate was 9.04. Stillbirths and infant mortality rates were respectively 32.2 and 36.2. Heart disease heads the list of all causes of death with a rate of 198, but 73 per cent of all deaths occurred after the age of 60. There was a decrease in deaths due to cancer, the rate being 117.

There was 1 case of smallpox during the year, and 1,682 individuals, mainly children, were vaccinated. Diphtheria cases numbered 19, 3 of which were fatal. Children who were immunized numbered 1,866. Scarlet fever presented a real problem with 211 cases and 9 deaths. There were 658 cases of measles and German measles, with no fatalities. Chicken pox and mumps numbered 479 and 536 cases respectively, with no deaths.

During the year, 241 cases of communicable disease were hospitalized at the Lincoln Hospital. Of these, scarlet fever numbered 132. There was a total of 5,968 patient days.

Medical calls on contagious disease cases totaled 1,907, and physical examinations of preschool and school children

numbered 4,500. Six hundred and fifty-six children were cared for at the dental clinic. A total of 1,663 visits were recorded at the venereal disease clinic, 105 patients receiving treatment.

The nursing division made a total of 9,280 home visits in the control of communicable disease, and tuberculosis visits totaled 2,077. Thirty-one hundred and ninety-six preschool children were served during the year, and 89,320 services rendered by nurses in the schools.

The laboratory examined 8,229 specimens, of which 1,697 were for diphtheria and 924 for tuberculosis. Besides routine examinations, work was begun on the culturing of scarlet fever cases in relation to release.—*An. Rep.*, Health Dept., Racine, Wis., 1931.

Ottawa, Canada—This city with a population of 130,672 in 1931 reports a birth rate of 23.4 and a death rate of 11.2. There were 11 deaths due to diphtheria as compared with 26 in 1930. An educational campaign for diphtheria prevention by toxoid immunization was carried on during the year. Posters were used in store windows and street cars, advertisements were used in newspapers, and literature was distributed to parents by nurses and through schools, and by lectures by the medical officer of health and the school physician.

Three toxoid clinics were conducted by the health department, and a fourth by a physician and the Victorian Order of Nurses. These clinics secured the immunization of 1,500 children during the year and stimulated an increase in the numbers applying to their family physicians for protective treatment.—*An. Rep.*, Medical Officer of Health, Ottawa, 1931.

**Honolulu, Hawaii**—In this city of 137,582 population, Palama Health and Welfare Center rendered important services in 1931. There were 44,616 visits to clinics, including 203 visits to the Mother's Health Clinic opened in July. There were 1,425 X-ray examinations for the Board of Health, and 623 others for junior high school pupils and other clinic cases. An excellent coöperative program has been developed with the support of the Medical Society. There were 37,605 home visits made by 17 public health nurses in behalf of tuberculosis, prenatal, child hygiene, and other cases. Child health conferences (15 weekly and 2 bi-weekly) are conducted jointly by the Palama nurses and doctors, and the Board of Health nurses. An active recreation program is also conducted. A newly organized tuberculosis committee, from August 1 to December 31, reached some 11,000 individuals through health education channels, besides 14,236 persons reached through the Christmas Seal Sale.—Palama Settlement, *Stat. Rep.*, 1931.

**Saving Eyes**—An excellent example of an attractive, well printed, and enlightening annual report is that of the National Society for the Prevention of Blindness. That progress is being made against ophthalmia neonatorum is suggested in the fact that in 1931 only 7.5 per cent of all new admissions to schools for the blind were victims of this disease, while in 1907 the figure was 28 per cent. Additional emphasis was placed upon eye tragedies resulting from inherited syphilis. During the year, the society gave 103 demonstrations of vision testing in 9 states and 42 cities, before 6,789 school and public health nurses, teachers, doctors, and social workers. In one state, 8,000 preschool children had their vision tested in accordance with the society methods and the results proved the importance of early eye examinations. Attention has been directed to the con-

servation of eyes of school children and aid has been given to the revision of the code for lighting school buildings. During the year, 22 additional sight-saving classes were organized, bringing the total number in the United States to 398, located in 23 states and 114 cities.—*Seventeenth An. Rep.*, National Society for the Prevention of Blindness, 1931.

**Knoxville, Tenn.**—The Health Officer calls attention to the fact that in 1924 there occurred in that city 296 cases of typhoid fever, resulting in 33 deaths and this was considered an average year. The economic loss resulting from this disease at that time amounted to 6.35 cents per capita. Early in 1925 an extensive program of sanitation was instituted which has cost the city about 10 cents per capita per year and has resulted in a reduction of 5.08 cents in the per capita cost of typhoid fever, such cost in 1931 amounting to only 1.27 cents. Thus the saving is ten times the yearly budget for all public health activities.

In 1931 the death rate in Knoxville was the lowest on record, 11.2 per 1,000 (excluding non-residents) and 12.6 was the crude rate. A comparison is afforded of the score of the health activities of this community over a period of years. In 1924 when the *Appraisal Form* was first utilized, Knoxville scored 351 points out of 1,000. By 1926, the score had increased to 610 and in 1931 the attainment was 697 points.

The Health Officer is to be commended for the excellency and simplicity of his annual report and the interesting charts which accompany the tables. A complete index makes the report of special value.—*An. Rep.*, Bureau of Health, Knoxville, Tennessee, 1931.

**Jerusalem**—The Straus (Hadassah) Health Center includes a program of health education, prenatal and infant welfare, nutrition, school hygiene, dental

hygiene, corrective gymnastics, child adjustment, and milk pasteurization supervision. Child guidance in the pre-school period is stressed. The center aims to be a place for testing forms and methods of health promotion in the widest sense, as well as for the application of methods which have stood the test. Education is the central motive.

In view of the lack of high grade milk for children, the center has equipped a modern pasteurization plant. For the first time in Palestine, as well as in the Near East, a high grade, inspected, bacteriologically controlled, pasteurized milk has been made available.

Because of the heterogeneity of the population, the center has found it necessary to experiment with methods of education. During the Pessach week in April, 1931, a graphic and pictorial exhibit was opened, presenting in colored posters, charts, and models, the essential facts of the modern knowledge of nutrition. "The vivid examples of right and wrong food and the consequences struck a convincing note in those who could not be easily influenced by language, written or spoken." The Health Center of Jerusalem is owned and maintained by Hadassah, the Women's Zionist Organization of America. It was made possible by a gift by Nathan and Lina Straus.—*First An. Rep.*, Straus Health Center, Jerusalem, 1931.

**Loose Milk**—"Is Loose Milk a Health Hazard?" Much valuable information regarding this question is contained in the report of the Milk Commission of the Department of Health of New York City. This commission, appointed at the request of the Commissioner of Health, was made up of eminent scientists and welfare workers. Loose milk is defined in the report as that portion of the city's Grade B milk

which is delivered in bulk. Nearly half of all the milk sold in New York is by this definition loose milk. Under this heading, of course, is included the large amount of milk used by institutions and for manufacture, but a large portion is used by restaurants, soda fountains and the like, to be dipped into glasses and served on the premises; and another class, representing about half of the bulk milk used, goes to retail groceries, delicatessen stores and similar establishments. These last two classes are particularly liable to contamination, and constitute the major part of the loose milk problem.

The commission, after extensive investigation, recommends that the sale of loose or dipped milk not consumed on the premises be prohibited, and that milk for consumption on the premises be dispensed only from bottles filled and sealed at the milk plant. However, in view of economic conditions, the restrictions are to be deferred until January, 1933, if the recommendations are adopted.

The Commission believes that the sale of loose milk represents a potential health hazard because of the greater opportunities for removal of cream or the addition of water, because the dipping method tends to give the first customers a disproportionate amount of the cream, and because the distribution by dipping from cans results in exposure to possible contamination.

All market milk should be protected by the additional safeguard of pasteurization, and thereafter kept in closed containers which are not opened until they reach the place at which the milk is to be consumed. . . . Even though the records of the health department disclose no cases of disease which have been traced definitely to the sale of loose milk, the commission believes, in view of the inferior quality, as shown by laboratory tests, and the greater chances of contamination, that loose milk is a potential health hazard.

# LABORATORY

## THE EFFECT OF VARIATIONS IN TEMPERATURE IN 37° C. INCUBATORS ON BACTERIAL COUNTS FROM MILK

ROBERT S. BREED, PH.D., F.A.P.H.A., AND CARL S. PEDERSON  
*New York Agricultural Experiment Station, Geneva, N. Y.*

DURING 1930-1931, the authors of this report, with the help of others,\* and with the coöperation of all of the important manufacturers of bacteriological incubators, made tests of commonly used bacteriological incubators. In the majority of cases, the incubators tested have been recent models loaned to us for test. While the results have been most disconcerting, they seem to open the way for a better standardization of bacteriological incubators for use in milk work that may do much toward solving some troublesome discrepancies. All milk control workers are familiar with cases where one laboratory almost continually reports agar plate counts higher or lower than some other laboratory that analyzes the same milk supply. Incubators apparently play an important part in causing discrepancies of this sort.

In the present studies, the bacteriological method of testing incubators first utilized by Supplee, Whiting and Downs† has been used and developed. They tested their incubator by pouring enough plates from the same sample of milk to fill the incubator. They then made counts from the plates, keeping a record of the position in the incubator of each plate and of such temperatures

as could be readily observed with the instruments at hand. After the publication of their bulletin, C. P. Olander of the Summe Dairy Company of Kansas City stirred our interest in the matter by sending us the record of a similar test of the bacteriological incubator that he was using. Both of these tests showed surprising discrepancies in counts due to the position of the plates in the incubator. The plates were heated too slowly in one incubator while they were overheated in the other.

The names of the incubators that were tested have not been given in the summary (Table I), partly because it was inconvenient, but chiefly because it was feared that the publication of these names without a more complete discussion than can be given here might leave false impressions.‡ If one incubator was listed as a No. 7 or as a No. 33 of some special type and our record showed that these incubators gave unsatisfactory results, a natural assumption would be that all incubators of the same make and number would give equally unsatisfactory results. It is not felt that such a conclusion would be justified for this assumes that the manufacturer has kept and will keep his models unchanged without improvements. From the interest shown by

\* Dr. M. O. Robinson of the Scott-Powell Dairies, Philadelphia, and Richard Eglinton of the Geneva City Department of Health, should receive especial mention for their valuable assistance.

† Cornell Univ. Agri. Exper. Sta., *Memoir 43*, 1921.

‡ For a more complete report. See the *Milk Plant Monthly*, 21:43 (Mar.), 1932; and the *Proc. 24th Ann. Convention, International Assn. Milk Dealers*, Laboratory Section, Oct., 1931.

manufacturers, some of whom have spent and will continue to spend much money in developing high class constant temperature apparatus, it is evident that the latter conclusion would be fallacious. Slight changes in the size or construction of incubators may make very noticeable differences in the results obtained.

Incubators of many commonly accepted types have been used in these tests, *i.e.*, water jacketed types made by the Wilmot Castle Co. and A. H. Thomas Co.; anhydric incubators made by the Freas Thermo-Electric Co., Chicago Surgical and Electric Company, Hearson Co., Electric Heat Control Apparatus Co.; and one home-made incubator. It was impossible to complete the tests of the DeKhotinsky and Lidberg models in time to incorporate the results in this preliminary report.

Only a few general statements can be made about results. In the first place, the incubators were tested under the most unfavorable conditions possible in that they were normally packed full of

agar plates. By so doing, their weaknesses were brought out in bold relief. Similar conditions are frequently found in those milk control laboratories that do not observe the standard specification that at least 1 inch of space be left between all piles of plates.

Wide discrepancies in counts and temperatures were produced under the conditions used in our tests. In one case (No. 2, Table I) about 800 plates were poured from one sample of milk and packed in an incubator. The highest average temperature was  $46^{\circ}$  C., the lowest  $37^{\circ}$  C. The average count obtained from plates placed in a carefully controlled  $37^{\circ}$  C. incubator was 38 per c.c. The highest count obtained from any plate of the 800 placed in the incubator under test was 62, the lowest 0. The sterile plates occurred at the hottest temperatures, the highest counts where the temperature was the lowest.

The way in which averages were computed is illustrated by Figure I in which a diagram is given of the lower right hand section of Incubator No. 2. The

FIGURE I.—Diagram of right lower section of Incubator No. 2 showing the arrangement of plates, the way in which averages were computed and the way in which temperature observations were made.

TABLE I

SUMMARY SHOWING RANGE OF PLATE COUNTS AND TEMPERATURES FROM VARIOUS INCUBATORS

Incubator Number	Type of heating	How filled with Petri plates	Maximum temperature Degrees C.*	Minimum count from any individual plate	Minimum average count †	Standard 37° C. count ‡	Minimum temperature Degrees C.*	Maximum count from any individual plate	Maximum average count
1	Two carbon lamps	3 high, spaced 1" apart	.....	2	23	.....	.....	134	128
2	Two electric plates on bottom	Packed full	46.0	0	0.5	38	37.0	62	38
2	Two electric plates on bottom	3 high, spaced 1" apart	38.5	25	60	88	33.0	144	120

\* Temperatures are approximated from the average plate counts and thermometer readings.

† Average count of all plates in a pile or tier as the case may be.

‡ Obtained by incubating a few plates in a separate incubator with carefully controlled temperatures.

minimum average count of any pile or tier in this section was the average secured for the second pile on the left hand side (1.5 colonies per plate) while the maximum average count of any pile or tier in this section was 33 colonies per plate obtained from averaging the results from all the plates in the back pile on the right hand side. Two thermometers were used in this section during the experiment. Their position is indicated in the diagram.

The temperature for each pile or tier was estimated by plotting a curve based on the number of colonies that appeared on duplicate plates incubated for 48

hours in carefully controlled incubators operated at a series of temperatures, such as 18°, 25°, 27.5°, 30°, 32.5°, 37° and 45° C. From the averages of the colony counts obtained in these incubators a curve was constructed on a percentage basis, the highest average count (usually found near 32° C.) being considered 100 per cent. From such a curve it was possible to estimate the temperature of any particular pile or tier in the 37° C. incubator by averaging the number of colonies that appeared on the plates in these piles and tiers. For example, where the average of a pile of plates was only 60 per cent

of the maximum average count secured from a series of incubators, the curve secured indicated that the actual temperature of the pile in the 37° C. incubator was 39.5° C. The temperatures observed from the thermometers placed in the 37° C. incubator agreed well with these estimated temperatures.

The samples used were ordinarily of pasteurized milk known to give the highest count at a temperature of 30–32° C. and these samples were known to be free of any significant number of thermophiles. A few raw milk samples were used.

In general, the water jacketed incubators never heated above 37° C. as their heating surface consisted of water at 37° C.; but they were slow in heating the plates and the plates rarely actually reached a temperature of 37° C. even at the end of 48 hours. Such conditions favor obtaining a high count from milk which has a flora that grows best at 30–32° C. Incubators of this type may be affected by very cold room temperatures. However, they yielded the most uniform counts of any of the incubators that were tested.

The anhydric incubators were found to heat quickly as their heating elements may be as hot as dull redness and the heat is carried to the agar plates by air currents. These conditions frequently cause overheating in some section of the incubator, a very unsatisfactory condition in making milk counts as a temperature of even 38° C. lowers the number of colonies that develop, and only a few degrees higher will yield almost sterile plates unless thermophiles are present.

The situation was particularly bad in those types of anhydric incubators that used carbon filament electric lamps as a source of heat, or electric heating plates covering the entire bottom of the incubator. There is no control over the convection currents in these cases, and the plates that are most directly exposed

to the heat are badly overheated. An improved situation is found in incubators where the heating elements are placed at the sides of the bottom or in hollow walls, thereby partially or quite completely controlling convection currents. Such incubators may show under- or over-heating unless the thermostatic control is carefully placed in relation to the convection currents.

Another type of anhydric incubator has the heating elements in 4 or more of the 6 walls, thus imitating the water jacketed incubator. However, greater variations in temperature occurred in these incubators than in the water jacketed types.

In the one type of incubator tested which had a forced draft, outside air was sucked in, heated and driven through at such a speed that it dried out the agar plates badly. Apparently it made a satisfactory drying oven and this was the primary purpose for which it was made. Some large size incubators with a slow forced circulation of the inside air have been described to us that appear to give more satisfactory results.

No incubator rooms have been studied as yet, but it is evident that these possess one advantage over all portable incubators in that they can never be packed to capacity, inasmuch as the center is always wide open thus allowing a free circulation of air. If the convection currents are properly controlled and certain shelves only are used, it is believed that they can be made to produce results that compare well with any of those given for portable incubators.

This work is to be continued until some general specifications can be drawn up for the *Standard Methods of Milk Analysis* report. It should be noted that the need for incubators that will produce a reasonably constant temperature of 37° C. with a fairly heavy load is even greater in routine milk control work than in ordinary bacterial work.

# EXAMINATION OF MILK FOR STREPTOCOCCI OF MASTITIS\*

CLAUDE S. BRYAN

*Department of Bacteriology, Michigan State College, East Lansing, Mich.*

THE examination of milk for streptococci of bovine mastitis is becoming more important from a public health standpoint as stricter sanitary milk control is demanded. The bacteriological or cultural method of milk examination is very important in the detection of udder infections and the determination of the relative extent of disease as indicated by the number of streptococci per c.c. of milk. Frost and Thomas<sup>1</sup> describe a technic for collecting and culturing milk samples which has been employed in this laboratory. Considerable care is necessary in carrying out the technic and the required help in culturing the samples is usually not available. Rosell<sup>2</sup> describes a technic which has disadvantages similar to that of Frost and Thomas and in addition extreme precautions in the collection of the sample are advised. There is a need for a rapid and accurate method of collecting and culturing milk samples with a minimum number of workers required. Such a method is herein described.

## SAMPLING

Satisfactory samples are obtained if they are taken in the normal environment of the cows. The udder and teats are wiped with a cloth moistened with an antiseptic solution. Two streams of milk from each quarter are collected in a strip cup and examined for physical evidences of mastitis. Then approximately 10 c.c. of the milk is collected directly into an ordinary sterile bacteriological test tube. The rapidity of the culturing technic makes it possible to

take individual samples from each quarter and thus immediately to detect the quarters that are infected. Proper care is exercised in transporting the samples to the laboratory where they are cultured as soon as convenient after collection.

## CULTURING

Each sample is inverted several times to insure thorough mixing of the milk and cream, after which 0.1 c.c. is placed in a sterile Petri dish, thus giving a dilution of 1 to 10. If desired, the cream layer can be used in culturing since many streptococci are carried up by the fat globules as they rise to form the cream layer. To each Petri dish is added, aseptically, 8 to 10 c.c. of gentian-violet liver infusion blood agar and rotated thoroughly to mix the agar and the milk. The plates are then incubated at 37° C. for 36 hours. Gentian-violet liver infusion blood agar was studied comparatively with gentian-violet veal infusion blood agar and also dextrose blood agar. The milk was diluted 1 to 20 and 1 to 100 for plating when the dextrose agar was used. The results are given in Table I. Photographs of cultures on each of these mediums are shown in Figures 1, 2, 3 and 4.

Preliminary experiments showed that 10 c.c. samples were as accurate as larger ones, so the collection of this size sample was adopted as standard procedure. The beef liver infusion agar introduced by Staflseth<sup>3</sup> and further developed by Huddleson<sup>4</sup> was employed with no change in composition. The pH of the agar was adjusted to 7.2 and filtration was effected through porcelain filter cotton. For convenience 250 to 350 c.c.

\* Journal Article No. 99 (n.s.), Michigan Agric. Exper. Sta.

amounts of agar were placed in 500 c.c. flasks and sterilized. To the melted agar cooled to approximately 50° C., was added sufficient 1 per cent aqueous gentian-violet so the final dilution of the dye was 1 to 150,000. Then aseptically collected bovine blood was added to make a 5 per cent blood agar.

Experiments performed using brilliant green as the inhibitory agent indicated that it could be substituted for the gentian-violet. Approximately 10 c.c. of agar is used per plate; with very little practice this amount can easily be poured. The dye in the agar inhibits the udder saprophytes and contaminants from the air at the time of collection of samples without affecting the growth of the streptococci. Figure 1 shows a sam-

ple of milk plated in liver infusion blood agar without any inhibitory agent while Figure 2 shows the same sample with gentian-violet 1 to 150,000 in the medium as the inhibitory agent. It is very often rather difficult to interpret accurately cultural results due to the vast number of organisms found in milk which culturally may resemble streptococci. The gentian-violet inhibits these non-significant organisms and thereby an accurate count of streptococci may be obtained. The comparative value of the different mediums is self-evident from the results in Table I. In each case the liver-infusion agar gave a higher count of streptococci than the other two mediums. Exact counts of streptococci in the dextrose blood agar are impossible

7	.....	.....	.....	.....	.....	2,540
8	3,175 (alpha)	.....	2,080 (alpha)	.....	1,760 (alpha)	2,050
9	2,540 (alpha)	.....	1,840 (alpha)	.....	1,210 (alpha)	1,965
10	3,810 (alpha)	.....	2,475 (alpha)	.....	2,480 (alpha)	1,965
11	300 (alpha)	.....	120 (alpha)	.....	180 (alpha)	1,090

since their differentiation from other organisms is based only on colony size and appearance.

Figure 3 shows a sample of milk from an infected cow cultured in gentian-violet liver infusion blood agar and Figure 4 shows the same samples cultured in gentian-violet veal infusion blood agar. There is a slightly higher incidence of streptococci and the colonies grow to a much larger size and thus demonstrate their characteristics more plainly on the liver infusion agar.

If culture isolations are desired they should be made immediately at the end of the 36-hour incubation period since later there is a danger that organisms may be killed by the acid formed upon the fermentation of the sugar and glyco-gen found in the liver. Pour plates are recommended but good results are obtained by placing 0.1 c.c. of the milk sample on the surface of the hardened agar and spreading the milk by the use of a bent glass rod.

#### CONCLUSIONS

1. Elaborate precautions in collection of milk samples for streptococcus examination are not essential; simply wiping the udder and teats with an antiseptic moistened cloth is sufficient.

2. Ten c.c. samples from each quarter or cow are representative.

3. Greater ease and accuracy in interpretation of cultural results are possible at the same time quantitative results are obtained.

4. Gentian-violet liver infusion blood agar is a superior medium to use in culturing milk for streptococci. Brilliant green may be substituted for the gentian violet.

## VITAL STATISTICS

**Occupational Fatality Rate Lowest in Twenty Years**—Greatly reduced industrial activity throughout the whole of 1931 resulted in the lowest death rate from accidental injuries arising out of or in the course of employment ever recorded for adult white male policy holders insured in the industrial department of the Metropolitan Life Insurance Company. The facts for a 20-year period, for which such records are available show this clearly.

Occupational fatalities during 1931 occurred at the rate of 27.3 deaths per 100,000 adult white male policy holders; a decline of 12 per cent from the rate of 31.0 per 100,000 for 1930. Each of the principal means of accidental injury showed a marked decline, as compared with 1930, with the exception of occupational automobile accidents, for which the rate increased 21 per cent. The rate in 1931 for all occupational fatalities was 0.2 deaths per 100,000 lower than that in 1915, and 2 deaths per 100,000 lower than in 1921, the years with the next lowest rates. These years, like 1931, were characterized by low business activity and widespread unemployment. In general, the insurance analysis shows that the curve for the occupational fatalities follows the curve of business conditions. The low rates for the years cited are in striking contrast to the high rates for 1913, 45.7 per 100,000; 1918, 40.9; and for 1923, 40.1 per 100,000. The high rate in 1913 exceeded the low rate in 1931 by 67 per cent.

Data for adult colored male policy holders are available only since 1921. Death rates for these policy holders were found to be from 2 to 15 per cent higher than those for white males in the corre-

sponding years, with the exception of 1931, when the rate for the colored dropped to 26.9 per 100,000 as compared with 27.3 for the white policy holders.

Traumatism by falls was the most frequently reported means of fatal occupational injury in 1931 among our adult white male policy holders. Deaths occurred through this means at a rate of 4.8 per 100,000. Closely following falls were automobile accidents with a rate of 4.6 per 100,000. Other important means of injury, in the order of their death rates were—traumatism by machines (3.1), traumatism in mines and quarries (3.0), steam railroad accidents (1.9), electricity (1.5), accidental drowning (1.3), and accidental burns (1.0).

Traumatism by falls was the leading means of occupational injury in each year since 1927, and also in the years 1925, 1924, and 1921. Steam railroad accidents were the principal means for the entire period 1912 to 1920, and again led the list in 1922, 1923, and in 1926. This change in the position of railroad accidents and traumatism by falls in recent years, was not brought about by an increase in the death rates for falls, which, on the whole, have fluctuated within fairly narrow limits in the 20-year period, but by the decline in the rate for railroad accidents. From the high point of 12.5 deaths per 100,000 in 1913, the rate for this type of accident has declined to 1.9 deaths per 100,000 in 1931. Much of this decline is undoubtedly real, and reflects a reduction in the accident hazard of railroad employees due to the safety measures introduced by the roads. But the extremely low rates recorded in 1930 and in 1931 must be ascribed in large meas-

ure to the very unfavorable economic situation of the railroads in these years, involving reduced traffic and fewer employees.

Industrial automobile accidents have come up from a place near the bottom of the list in 1912, to second place in the years 1930 and 1931. In the latter year, the rate (4.6) was but 0.2 deaths per 100,000 behind the rate for falls. If the present tendency continues, automobile accidents will soon be the leading means of fatal occupational injury.—Met. Life Ins. Co. *Stat. Bull.*, 13: 1-2 (Mar.), 1932.

**Preliminary Report of Vital Statistics for New Jersey, 1931**—The preliminary report of vital statistics for New Jersey shows that the low general death rate and infant mortality rate of 1930 were maintained in 1931. The general death rate of 10.63 in 1931 was identical with the rate for 1930, which rate was the lowest recorded in the state since the establishment of the State Department of Health 54 years ago. The previous low rate had been 11.43 for 1927. The infant mortality rate was 56.9 per 1,000 live births, which was only slightly higher than the lowest rate ever attained in the state. The lowest rate, 56.7, occurred in 1930.

Approximately 64,050 births were reported in New Jersey in 1931, showing a birth rate of 15.43 per 1,000 inhabitants. The total births show a decline of approximately 4,150 births from the number reported in 1930. This decrease of more than 6 per cent is the greatest decrease in births which the state has suffered at any time since 1878, when the reporting of births became obligatory.

New low levels in death rates from typhoid fever, diphtheria, and tuberculosis were reached in 1931, when the rates were 0.9 for typhoid fever, 2.9 for diphtheria, and 65.1 for tuberculosis (all forms). The maximum typhoid fever death rate in New Jersey was experi-

enced in 1882 when the rate was 74.3. Since 1912, the annual death rate for this disease has not exceeded 10 deaths per 100,000 population.

The death rate from diphtheria for 1888 was 148. During the decade beginning with 1900 the rate declined from 48 to 25. The following 10-year period showed a decline to 18.

The rate of 65.1 for all forms of tuberculosis in 1931, compared favorably with the rate of 90.1 for this disease 7 years ago. The death rate from cancer and other malignant tumors was 113.5 in 1931. This cause of death has increased gradually in importance, since 1879 when the death rate was 37 per 100,000.—*Pub. Health News-Monthly Bull.*, Dept. of Health, New Jersey. 17: 45-6 (Feb.-Mar.), 1932.

**Vital Statistics in Porto Rico, 1930**—The enumeration of the census of Porto Rico in 1930 made possible the thorough revision and correction of the vital statistics of the island, for the last 20 calendar years, beginning with 1911. As compared with the fiscal year, the calendar year is a much more logical and generally accepted basis for estimating vital statistics figures; this basis makes the figures for Porto Rico more comparable to those of the world at large.

The death rate for Porto Rico in 1930 was 18.6 per 1,000 population as compared with 25.3 for 1929 and 23.6 for 1928, when the rate was increased as a result of the San Felipe hurricane which occurred during the latter part of 1928. With the exception of the years 1917 and 1918, when the general death rate was 30.9, because of the severe epidemic of influenza and measles, the years 1928 and 1929 showed the highest death rates in the last 20 years.

There were 54,574 births registered in 1930 as compared with 52,468 the previous year; the birth rates for 1929 and 1930 were 34.4 and 32.2 respec-

tively. Marriages in 1930 numbered 9,961, the marriage rate being 12.8 per 1,000 population, as compared with 10.9 in 1929. Infant mortality which had flared up along with the general death rate in 1928 and 1929 to 167 and 161 for those years, respectively, declined in 1930, to a rate of 126 per 1,000 live births.

While the health conditions in Porto Rico are by no means satisfactory, it is indeed gratifying to note a reduction, and in some cases a great reduction in the deaths from several causes. Seven causes of death showed reductions of more than 30 per cent, the greatest reduction being noticed in the death rates from dysentery (80 per cent); hookworm disease (53 per cent); influenza (68 per cent); and diarrhea and enteritis, which declined 35 per cent among children under 2 years of age, and 47 per cent among those 2 years and over. The 1930 death rate from diarrhea and enteritis among children under 2, was 195 as compared with 284.6 in 1929; for children of 2 years and over, 132.2 in 1930 as compared with 249.9 in 1929. The death rate for malaria declined from 137.9 in 1929 to 121.08 in 1930; congenital debility from 107 to 84.2; bronchitis from 80.9 to 57.6; dysentery from 33.5 to 6.6; nephritis from 205.6 to 133.8; bronchopneumonia from 125.9 to 97.9; typhoid fever from 14.5 to 8.5; hookworm disease from 50.4 to 23.7; influenza from 10.4 to 3.3; and tuberculosis (all forms) from 301.4 to 263.2.

As can be observed by the high mortality rate from tuberculosis this disease is a very important public health problem in Porto Rico, and as such it is engaging the interest and attention of the health authorities of the island. Among the important activities in the control of tuberculosis are the better provision for hospitalization of the advanced cases; the care of 30 children at the Preventorium at Guaynabo; the provision of milk for the children at-

tending the rest rooms for undernourished children in San Juan and in the camp for undernourished children at Aibonito; and the maintenance of milk stations in practically every town on the island.

Heart disease, cancer, and external causes were the only important causes of death which showed increases in 1930, over the previous year. This is typical of the experience in most other countries. —*Report of the Commissioner of Health of Porto Rico. Fiscal Year Ending June 30, 1931, pp. 13-22.*

**Report of the Registrar-General of the Irish Free State for the Year 1930**—The estimated population of the Irish Free State in the middle of the year 1930 was 2,946,000, the same as for 1929, but 26,000 less than the population disclosed by the Census of 1926. Marriages and births registered during the year show increases, and deaths and emigration show decreases as compared with 1929, the decrease in net emigration being 5,238. The number of marriages was 13,631, and the marriage rate was 4.63, as compared with a rate of 4.61 in 1929, and the annual average, in the last 10-year period 1920-1929, of 4.86. The marriage rate of the Irish Free State is low as compared with the other countries of Great Britain. In Northern Ireland, the rate for 1930 was 6.07 per 1,000; in England and Wales 7.9; and in Scotland 6.89.

The birth rate for the Irish Free State in 1930 was 19.81 and in the preceding year 19.78. Although the 1930 rate is slightly higher than the rate for 1929, the increase is so small as to compensate very little for the gradual but steady decline in birth rate that has been noticeable in recent years. Between the periods 1911-1915 and 1925-1929 there has been a fall of 9.7 per cent in the birth rate.

The number of deaths registered during the years was 41,702, or 14.16 per

1,000 inhabitants. This is the smallest number of deaths ever recorded for a single year in the country, but on account of the decline in population the rate is not the lowest on record. Lower rates have been reported twice within the last decade—14.01 in 1923, and 14.06 in 1926. The death rate for tuberculosis continues to decline, although the rate for the Irish Free State is still high as compared with other countries; it was 129.8 in 1930 as compared with 131.5 in 1929. The tuberculosis deaths in 1930 constituted 9.2 per cent of the total deaths for the year.

There were 213 more deaths from cancer in 1930 than in 1929, increasing the death rate from 105.8 in 1929 to 113.0 in 1930. The cancer record for 1929 had been encouraging because the rate that year had shown a decrease from 108.2 in 1928.

Deaths from diseases and accidents of pregnancy and childbirth numbered 278 or 4.77 per 1,000 births registered as against an average of 295, and a rate of 4.82 per 1,000 births in the 10 years 1920-1929. The infant mortality rate for 1930 was 68, as compared with 70 for the preceding year and 71 as the annual average for the preceding 10-year period.—*Annual Report of the Registrar-General of the Irish Free State for the Year 1930.*

**Infant Mortality in 1930**—The infant mortality rate for the 860 cities in the birth registration area of the United States in 1930 was 62.2 per 1,000 live births or 4.0 points below that of 1929 when the rate for 720 cities was 66.2. The 1930 rate is thus the lowest yet attained for the cities of the country.

Among the largest cities, those over 250,000 population in 1930, the lowest rate reported is for Seattle, Wash., the figure being 37. San Francisco, Calif., stands next with a rate of 40, and Portland, Ore., third with a rate of 41. In

the population group 100,000 to 250,000, Long Beach, Calif., is low with a rate of 43. Tacoma, Wash., is next with 44, and Elizabeth, N. J., third with 45. Within the group of cities with populations of 50,000 to 100,000, Oak Park, Ill., with a rate of 28 is first, followed by Glendale, Calif., 30, and Newton, Mass., 31. Of the cities between 25,000 and 50,000 population, Alameda, Calif., with a rate of 21 stands first. Everett, Wash., with 27 is second, and Hutchinson, Kan., with 30 is third. In the group of smallest cities, those with 10,000 to 25,000 population, Shorewood, Wis., has an infant mortality of zero. Maplewood, Mo., has a rate of 6, and Webster Groves, Mo., 9.

It is interesting to note that the list of 15 cities (3 from each population group) having the lowest infant mortality in 1930, includes 8 cities located in the Pacific Coast states; the list of 15 cities (3 in each population group) showing the highest rates, includes 8 cities located in the southern and southwestern states, 4 in Tennessee alone.

When the cities are grouped by population, the largest cities are found to have the lowest average infant mortality rate. These rates are computed from the sum of the births and the sum of the deaths under 1 year. For the group of cities with 250,000 population or more in the birth registration area, the rate in 1930 was 60.0. The smallest cities as a group have the highest rate, 66.6. This fact confirms the experience of previous years.

Infant mortality rates in the birth registration area show a wide variation from zero at one extreme to 259 at the other. About a quarter of the cities have rates below 50. Not quite half have rates between 50 and 70. Nearly a third have rates above 70. Of the 10 largest cities in the country in 1930, Chicago and St. Louis had the lowest infant mortality rate, 54 for each city. Cleveland stands next with a rate of 55,

and New York fourth with 57. Next comes Philadelphia with a rate of 59, followed by Los Angeles (61), Detroit and Baltimore (65), and Pittsburgh and Boston (69). Of these 10 cities, Boston alone showed no reduction in infant mortality from 1929 to 1930, the rate

for both years standing at 69. The 9 other cities in the group showed reductions varying between 3 and 11 per cent. The reduction of 11 per cent was for Baltimore, which had an infant death rate of 73 in 1929.—*Stat. Rep. Infant Mortality*, A. C. H. A., 1930.

## PUBLIC HEALTH ENGINEERING

**The Sewage Works of Essen-Rellinghausen and the Operation of the Latest Extensions**—The plant deals with a dry weather flow of 30,000 cu.m. per 24 hours. The strength of the sewage is similar to that of an average domestic sewage. The trade waste waters included are mainly from coal mines, iron works, dye works, and laundries. Preliminary treatment is accomplished by screens, sand and oil traps, Emscher tanks, and a flat clarification tank with separate sludge digestion tanks, and further treatment in an activated sludge plant. The units of the plant are described and illustrated.

The material deposited in the sand trap is treated with compressed air to separate sludge. The oil trap consists of an aeration chamber, from which the sewage overflows into stilling chambers where the floating oil is retained by walls under which the sewage flows back to the aeration section. The collected fats are either burned with the screenings or digested with sludge. The Emscher tanks are 20 years old and, in spite of much overloading, have given no trouble. The water content of the sludge varies according to the amount of excess activated sludge which is returned to the plant.

The flat clarification tank is fitted with Dorr sludge scrapers and a scum

remover and double inlet and outlet weirs to increase the tank capacity when the flow is increased by rain. For experimental purposes, one digestion tank was built flat, with a Dorr sludge remover, and another with a floor inclined downward toward the center. Both are fitted with submerged gas covers, stirring apparatus for breaking the scum, and heating and stirring arrangements.

The tanks are now being used in sequence, artificial heating being used in the first stage only. Scum has formed above the gas cover in the first tank but not below the cover.

The effect of clarification and digestion on the amount of sludge and on its water content and the effect of temperature on the amount of supernatant water are discussed. The sludge gas beyond what is used for heating the digestion tank is added to the city gas supply. The gas amounts to an average of about 16 litres per head per day and would be sufficient to supply the power needs of the plant. Gas from the Emscher tanks contains considerably less carbon dioxide than that from separate digestion. Hydrogen sulphide (due to sulphate from mine drainage) is removed by passing through bog iron ore. Sludge is deposited on drying beds in wet weather but otherwise on fields.

A drum screen in the channel leading

to the aeration tank is brought into action when required to prevent Chironomid larvae reaching the activated sludge plant. There are 4 aeration tanks using a combination of compressed air and submerged paddles. Porous plates suitable for such aeration are discussed. Two 8 m. deep hopper-shaped settling tanks have been found to give less operation trouble and better results than one 6 m. deep with double hopper bottom. Return sludge and dilution water containing oxygen are added in the channel leading to the aeration tank.

The power requirements and effect of the activated sludge treatment, and the plant for burning screenings and oil-trap residue are described.—F. Fries, *Gesund. Ing.* 54:661 and 681, 1931. *Summary of Current Literature, Water Pollution Research V*, 2 (Feb.), 1932.

**A Review of Water Treatment by Ammonia - Chlorine Process**—The development of ammonia-chlorine treatment for taste control is discussed. It was adopted at Indianapolis in 1930, anhydrous ammonia being applied to the raw water just prior to its chlorination. Owing to certain difficulties in handling the anhydrous ammonia, it was decided to use the cheaper ammonium sulphate instead. This has given entire satisfaction. It is applied mixed with aluminium sulphate. The ratio of ammonia to total chlorine has varied from 1:2 to 1:3, the ammonia dose ranging from 2.3 to 3.1 lb. per mil. gal. The sulphate used normally contains 0.003 per cent of phenol.

The results of this treatment are better disinfection, elimination of phenol tastes and of some of the other tastes resulting from chlorination, elimination of aftergrowths, the maintenance of a higher chlorine residual without noticeable tastes, and probably a reduction in the total chlorine requirement.

Experience has shown that a fairly

hard water containing an appreciable quantity of calcium responds readily to the treatment and that corrosion is not accelerated.—H. E. Jordan, *Water Works Eng.*, 84:1388, 1931. From *Summary of Current Literature, Water Pollution Research, V*, 3 (Mar.), 1932.

**Modern Sewage Disposal Exemplifies Chemical Engineering Progress**—The author deals with the growth of mechanization in sewage treatment and discusses the design and use of screens, grit chambers, Imhoff tanks, and settling tanks with mechanical sludge removal. Aeration and agitation methods used in the activated sludge process are described and the possibilities of value of recovery from sludge as fertilizer or in other ways are discussed. The author then deals with separate sludge digestion, the composition, amount and utilization of sludge gas, the effect of temperature and pH on digestion, thermophilic digestion, and the drying or dewatering and use as fertilizer of digested sludge.

Present research is directed toward the concentration of fresh solids before digestion, rapid digestion at high temperature, mechanical dewatering of digested sludge and its disposal at the lowest possible cost.—F. W. Mohlman, *Chem. Metall. Eng.*, 38:520, 1931. From *Summary of Current Literature, Water Pollution Research, V*, 2 (Feb.), 1932.

**Methods and Aims of Agricultural Utilization of Sewage in Central Germany**—The industrialization of central Germany in the last 20 years and the resulting increase of population are briefly described. The region is one with a fairly low average rainfall so that there is little natural reserve of water to meet increased demands. The supply must be drawn from ground water as the rivers are in general too polluted for use. Impounding reser-

voirs and central water works are being used wherever economically possible. Damming the rivers, as is being done on the Ruhr, would have little effect on the supplies, which are mainly ground not ground-filtered water, and would not have the same purifying effect as the pollution is largely organic and putrescible matter.

The agricultural utilization of sewage is therefore of importance. By this means the ground water supply is supplemented and damage to land by the withdrawal of ground water is prevented.

König has calculated that good results can be obtained by utilizing town sewage at the rate of 2,000–5,000 cu.m. a year per hectare, depending on the condition of the soil. These quantities would, taking into account the increased wastage by evaporation and seepage, make up the average yearly 400–500 mm. rainfall to the optimum for the crops grown of 600–700 mm. These quantities of sewage can be easily assimilated by the soil. The choice of process (artificial rain or irrigation) depends mainly on the contour of the surface, irrigation used on slopes and artificial rain on flat or uneven land.

The suitability of town sewage and various industrial waste waters as fertilizer and methods of irrigation and artificial raining are discussed. The pre-treatment necessary varies from coarse screens to settling plants with 1–2 hours' retention. Where new plants are necessary, settling tanks with 15–20 min. retention, with separate digestion tanks of 20 litres a head capacity are recommended. Settling tanks to retain the sewage about 1 month are necessary when frost renders agricultural utilization impossible.

The control of the distribution of sewage, the operation of the plant, and the financial arrangements are discussed. The processes of purification of the

sewage in the ground are described and the absence of hygienic objections to the agricultural utilization of sewage is emphasized.—A. Carl, *Gesund, Ing.*, 54: 765, 1931. From *Summary of Current Literature, Water Pollution Research*, V, 5 (May), 1932.

**Water Supply and Sewage Disposal in Cairo, Egypt**—Egypt has a total population of 14 million, mainly rural. There are 28 water works filtering surface water, and 22 untreated supplies from wells. The supplies are under the control of the Department of Public Health. The demand averages 30–35 gal. per head per day.

The Cairo supply for a population of 800,000 is drawn from the Nile. The content of suspended matter varies from 150 to 1,500 p.p.m. Alum is added at the intake pipe and the water is pumped to settling tanks. Fifty per cent is treated in primary tanks with Dorr clarifiers and then in secondary tanks, while the remainder passes direct to secondary tanks. The water is then passed through rapid sand filters with air-water wash, and chlorinated.

Algae growths in the river cause trouble and copper sulphate treatment has not been beneficial. Sewage is of a strong domestic type and disposal is generally by sewage farming. The sewage is generally pumped for some distance and is septic, causing corrosion in sewers and odor nuisance. The Cairo sewage is pumped 15–20 miles and treated in Travis tanks.

Sludge is dried on sand beds and sold for fertilizer. The effluent is used on the state farm. About 1 per cent is treated on stone filters. Some chemical results are given.—J. Heukelekian, J. Series Paper, New Jersey Agri. Exper. Station, New Brunswick, reprinted from *Pub. Works*, Mar., 1931. From *Summary of Current Literature, Water Pollution Research*, V, 5 (May), 1932.

Moreover these studies do not account for acclimatization. For these reasons the authors have undertaken the problem of the establishment of optimum conditions for light and heavy work.

It is pointed out that until perspiration sets in, skin temperature runs parallel to the sensation of heat and that a definite subjective sensation of warmth or cold corresponds to a definite skin temperature. For this reason the authors believe that skin temperature represents the objective index, both of the thermal effect and subjective sensation. They quote Marshak to the effect that the normal range of skin temperature of man at rest is between 31.5 and 33.5° C. So long as the skin temperature remains in this range the subject is comfortable, neither hot nor cold.

In the experimental studies they determined the optimum conditions for light and heavy work which do not result in the production of perspiration, and utilize the temperature of the forehead and sternum as indexes. In the range of perspiration use was made of a method of W. L. Minor, for the quantitation of the degree of perspiration present. In this technic the forehead is covered with a light coating of a mixture of iodine, alcohol, and castor oil, and is then powdered with rice starch. They have designated 6 degrees of perspiration:

1. Separate dots
2. Large dots
3. Spots and dots
4. Small patches
5. Large patches with confluence
6. Profuse washing away of starch

The authors have established the fact that in every given phase of perspiration the subject experiences a corresponding sensation of warmth. The light work experiments were conducted on seamstresses, the skin temperatures being recorded by means of a resistance thermometer. It was found that the skin temperature closely followed the room

temperature and that the sensations of the subjects closely followed the skin temperatures. At room temperatures lying between 18 and 22° C. the skin temperature was found to be in the comfort range. A table is prepared showing the relationship between dry bulb temperature, humidity, and the air velocity necessary for optimum air conditions.

The heavy physical work experiments consisted in raising and lowering a 16 kg. weight. A table is presented showing the optimum air conditions for the conduct of such heavy physical labor.—G. D. Arnaoutow and E. W. Weller, *J. Indus. Hyg.*, 14, 4 (Apr.), 1932.

L. G.

**Malignant Growths Resulting from Exposure of Radioactive Substances**—Up to this time there have been some 18 fatalities among workers engaged in the painting of watch and clock dials with radioactive substances. Among these persons 2 deaths were brought about by bone sarcomas prior to 1929—1 in 1924 and 1 in 1927. Since 1929, 3 more deaths from bone sarcoma and 3 additional cases of this disease have been reported.

Dr. Martland points out that there appears to be a decided difference in the clinical and autopsy findings in the early cases as contrasted with the later ones which have occurred since 1929. The first 13 deaths which occurred between the years 1922 and 1928 developed in from 4 to 6 years after cessation of employment. These cases were characterized by the development of anemia and necrosis of the jaw bone.

In the later cases, occurring in a period from 6 to 7 years from the termination of employment, the patients appeared to have escaped extensive necrosis of the jaw bone and the fatal anemia, and instead showed chronic crippling bone lesions, most frequently present in bones subjected to weight, pressure, or trauma. Anemia is also present in these

confinement, traumatic neurosis, and the preparation of standards for the recognition of injury, disease or death due to occupational causes. There were likewise lectures on occupation and eyesight, and standards of nutrition and standard diet.

The meeting was attended by more than 100 persons, including government officials and factory physicians. The next annual meeting will be held in Tokyo.—*Indust. & Labor Inf.*, 41, 4: 75 (Jan. 25), 1932. E. R. H.

#### Pulmonary Fibrosis: Experiments of Short Duration—Authors' Conclusions:

It seems probable that the fibrosis of the lungs produced in workers exposed to dusty atmospheres, especially those in which fine particles of silica make up the larger percentage of the dust, is an end product and represents a progressive defeat of the protective mechanisms of the body. It is never found until the lung fails to rid itself of dust carried out of the bronchi by ciliary action or of dust carried through the lung by way of the lymphatic channels. With the breakdown in the carrying mechanisms, the burden of protection is the phagocytic cell, which, with its load of engulfed material, passes to all parts of the lung and ultimately becomes immobilized in those portions of parenchyma in which lymphatic tissue is abundant. The cells concerned are polymorphonuclear leukocytes, which are the first to appear, to disintegrate and to disappear, and clasmotocytes, which appear later, are extremely active, break up less readily, and may become transformed into fibroblasts. In association with the tissue fibroblasts the clasmotocytes form scar tissue.

Finally, fibrosis is the result of the action of substances secreted by the cell on the foreign particles. If a tissue poison results from this chemical action, fibrosis is encouraged, and is progressive, lasting as long as the unaltered irritant remains in the lung.—

Willis S. Lemon and George M. Higgins, *Am. J. Med. Sci.*, 183, 2: 153-164 (Feb.), 1932. E. R. H.

**Anthracosis and Silicosis**—Sir William Jenkins asked the Home Secretary what number of men had claimed compensation who were suffering from sili-

cosis in South Wales; the number who succeeded in their claim; and the number refused, if any, and upon what grounds. Sir Herbert Samuel replied: "Separate figures for South Wales are not available, but the Returns for Great Britain show that in 1929 there were 12 cases, and in 1930, 18 cases of coal miners who recovered compensation for disablement from silicosis. The Returns for 1931 are only now being collected. I regret that I am not in a position to give the total number of claims made or refused, or the reasons for refusal."—House of Commons (Feb. 11), *Lancet*, 5660: 430 (Feb. 20), 1932. E. R. H.

**Industrial Hygiene**—A serious silicosis hazard was found at a plant in Maryland which was engaged in crushing and screening quartz for use in various industries. Atmospheric dust tests revealed extremely high concentrations of quartz dust consisting of practically 100 per cent free silica under 10 microns in size. The investigation was made by Dr. B. F. Meriwether, Surgeon, U. S. Bureau of Mines, and J. J. Bloomfield, Asst. Sanitary Engineer, U. S. Public Health Service. Physical examination of employees exposed from 4 to 30 months showed a percentage of defectives which was more than twice as great as those encountered by the examiner in the majority of small industries, although the shortness of the period of exposure did not reveal much positive evidence of silicosis. Nevertheless one of the officials of the plant, whose period of exposure had been longer, died recently from silicosis after less than a year's confinement to bed.

The methods used for eliminating the dust hazard were extremely crude and practically worthless. Recommendations were made for the installation of an efficient dust collector of the cloth-screen or bag type and the enclosure of all grinding machinery, screens, elevators, and conveyor pipes with an ex-

haust ventilation system. Emphasis was placed upon selecting workmen free from defects predisposing to silicosis and that preference be given for those under 40 years of age.

A study was made of the lead hazard in acetylene-torch operation in the cutting of steel plates coated with red lead at the ship scrapping plant of a company at Curtis Bay, Md., where an acute case of lead poisoning occurred. Even though most of the work is conducted out of doors, a compressed air respirator was recommended, since much of the work had to be done in confined spaces aboard ship.

At the Maryland State Normal School acute symptoms of amyl acetate irritation developed in a painter engaged in spray painting without the protection of a booth and exhaust ventilation. An inspection showed that the usual hazards of spray painting (health as well as fire) could be removed.—*Ann. Rep., State Board of Health of Maryland, 1930, pp. 191-195.* E. R. H.

**Refrigerants Tested for Toxicity**  
—At the Atlanta Meeting of the American Chemical Society the first report was made concerning dichlorodifluoromethane, which was described as a non-toxic refrigerant. Subsequently, certain characteristics of this material, which has become known to the trade as Kinetic No. 12, or as F 12, have been determined and the results given considerable publicity.

Tests were made covering 10 of the commonly used refrigerants, subjecting animals to the same for varying periods of time (shown in tables) with the conclusion that the new refrigerant named above was the least toxic.

The results of the tests here discussed show, according to the report, that practically the only hazard which may be introduced with the use of this new refrigerant occurs when vapors come into direct contact with an open flame or high temperature, and are decomposed. Obviously, such a hazard would be

decreased in the absence of circulation of the atmosphere, which would bring the heavy vapors into contact with the flame or hot surface, and where there was customary ventilation of the room. In any event, the harmful products of decomposition would be pungent and irritating so that even minute amounts would give ample warning. It seems almost beyond the limits of probability that there would be present any person who could not or would not recognize the warning gases and either ventilate the room or leave it long before experiencing either prolonged exposure or concentrations dangerous to health.—

*Indust. & Eng. Chem., News Edition, 10, 1: 3-4 (Jan. 10), 1932.* E. R. H.

### Gases that Occur in Metal Mines

—The gases found in metal mines some of which are explosive and some health-hazardous are methane, hydrogen, carbon dioxide, those of sulphur and nitrogen, carbon monoxide, and, where fires occur, the oxides of arsenic, antimony, etc. In addition very finely divided dusts exist.

A discussion is given of these substances and reports concerning them in the different mining districts of the country. Precautions against gases found in metal mines with recommendations providing against fires and the control of ventilation, temperature and humidity are discussed, likewise the methods for the detection of gases and especial respiratory protection against them.—D. Harrington and E. H. Denny, U. S. Bureau of Mines, *Bull. 347, 1931, 21 pp.* E. R. H.

**Time Loss in Mississippi Factories**—Reports were received by the Bureau of Industrial Hygiene and Factory Inspection from 10 factories in Mississippi for 1931 which revealed time loss of 4,511 days.

In preventing illness among factory employees, the state factory inspector made physical examinations of 855 factory workers and vaccinated over 2,000 workers—a service available to any factory desiring it. Numerous safety de-

vices were installed to prevent accidents. Occupational diseases are not a big problem in Mississippi factories, although a few are reported each month.—Felix J. Underwood, State Health Officer, *Weekly Health Suggestions*, Mississippi (Received Dec. 1931).

E. R. H.

**Rates of Physical Impairments in 28 Occupations, Based on 17,294 Medical Examinations**—In a previous study it was shown that the rates of physical impairment in a group of skilled workers tended to be definitely higher than in other groups (professional, business, agricultural). The present study has found that the higher rates are not to be explained, except in a few instances, as due to the hazard of any specific occupation.

"On the contrary, these higher rates seemed to be the result of various factors associated with social, educational, or economic causes, and to be present, in more or less degree, in every specific occupation studied."—Rollo H. Britten, *Pub. Health Rep.*, 47, 1: 1-25 (Jan. 1), 1932.

E. R. H.

**City Noise**—All interested in industry will be interested in this volume which is too extensive for abstracting. Among other features are: "What Noise Does To Us," Noise Measurement, Noiseless Progress, Practical Remedies and Finances. A number of interesting radio talks are also included, with papers by specialists.

The scale of noise levels ranges from a threshold intensity of 1—the least sound change heard by the normal ear—to 10 billion times that amount of noise representing a range from 0 to 100 decibels. A table makes clear the difference between loudness, as measured by the ear (decibels) and intensity, as measured by electrical instruments. A normal conversation, carried on at a distance of 5 feet, has a loudness of about 60 deci-

bels. A small difference in the loudness as expressed in decibels means a tremendous difference in the intensity involved.

A measurement of maximum noise levels from specific sources showed a passenger automobile (quiet) to produce 65 decibels, thunder (1 to 3 miles) 70, radio loud speaker 81, street car 83, roaring lion 87, motor truck 87, elevated train 91, subway 97, riveter 101, automobile horn 102, and hammering on steel plate (almost painful) 113.—Noise Abatement Commission, New York City, Department of Health, 308 pp., 1930.

E. R. H.

**Report of the Senior Medical Inspector of Factories**—The outstanding feature of the year has been the closer coöperation of the activities of the department with research work. It is recognized that the progress of industrial medicine as a scientific branch of medicine depends on the correlation of the study of conditions found in industry with laboratory observations.

Notifications of various occupational diseases are summarized in a table with comparison of figures for years from 1900 to 1930. In the latter year there were 265 cases of lead poisoning with 32 deaths, 3 of mercurial poisoning, 1 of arsenical poisoning, and 24 of aniline poisoning, 43 anthrax cases with 6 deaths, 194 cancerous cases (epitheliomatous ulceration) due to pitch, tar, and oil including 36 deaths, and 95 cases of chrome ulceration, most of which occurred in chromium plating although there were 15 reported in dyeing and finishing.

In connection with paint spraying the opinion was expressed that it was not necessary for efficient work to produce such quantities of air and paint as to produce a visible cloud. The amount of spray produced appears to depend on the adjustment of air and point delivery from the "gun" and the differences in density of the cloud are remarkable.

Among the anilin poisoning cases were 10 following the inhalation of vapor from 5-chlor-ortho-toluidine, the first thus far recorded. Within a day the workers reported slight headache, drowsiness and eye and throat irritation. Later serious effects were observed which caused 10 men out of 13 to cease work suffering from painful urination with bloody urine.

A table is given for the anthrax cases showing the locality, age, sex, occupation, severity, situation on the body, the material handled, the treatments, and remarks. Of the cases, 24 were incurred by handling hides and skin, 13 from wool, 1 from horse hair, and 5 in other industries.

There were reported 789 cases of dermatitis. This affliction has been steadily mounting in the last 5 years. It is considered that dermatitis can and must be reduced to a handful of cases yearly, but this can be accomplished only by carrying out to the letter the advice in the official pamphlets and placards. A large number of cases is due to the method of cleansing the hands and arms after work which could be largely prevented by coating the skin preliminary to work with a fine film of ointment which will prevent the entrance of stains. In many cases injury of some type preceded the dermatitis while in many others "dermatitis succeeded sepsis."

According to the registrar files, there were 700 certificates of deaths due to pulmonary fibrosis of which number silicosis was mentioned as a cause in 241 which occurred in the following industries in 1930—pottery 52, sandstone 49, coal mining 39, grinding 36, gold mining 23, refractories 12, sand blasting 10, tin mining 10, lead mining 2, granite 2, mining engineering 2, scouring powders 1, slate quarrying 1, file cutting 1, and leather dressing 1.

There were 20 fatal cases of asbestosis without tuberculosis, in 18 of which

a post-mortem examination was made. Of these 20 cases, 6 were mattress makers and 6 were carders or cloth weavers. The average age of death of these 20 cases was 38.9 years, and the average length of employment was 14.9 years. Despite the technical difficulties encountered in suppressing the dust in certain processes, it is believed that prevention of the disease is possible.

There were 133 case reports involving fumes and gases, 17 of which were fatal. Of these 94 were due to carbon monoxide, 2 to carbon dioxide, 5 to sulphuretted hydrogen, 4 to sulphur dioxide, 5 to chlorine, 5 to nitrous fumes and 6 to benzol (one of the latter being fatal). Artificial silk works among others were involved in both sulphuretted hydrogen and chlorine poisoning.

At a large aircraft works women were employed spraying cellulose paint on metal framework in a large shop ventilated as a modern dope shop by frequent changes of air. One of three women examined showed the presence of punctate basophilia of some considerable degree, together with epistaxis.

The effects of a cellulose paint said to contain 15 per cent benzol, sprayed by women in cabinets with localized exhaust, were studied clinically and hematologically, with the result that the only almost constant finding was faucial congestion, and this was not confined to those on spraying operations. No constitutional symptoms or results suggestive of benzol (or homologues) absorption were recorded. A more detailed examination seems to endorse the previously expressed opinion that with a moderate temperature and good localized exhaust ventilation, cellulose spraying has not affected the health of such workers. In a few cases where there has been complaint, a rapid improvement was noted with betterment of ventilation and a lower temperature. The occurrence of complaints bears a definite relation to conditions of work, but not to the percentage of benzol (or homologues) contained in the material sprayed.—

John C. Bridge, Senior Medical Inspector of Factories, *Ann. Rep. for the Year 1930*, pp. 94-122.

# FOOD AND NUTRITION

## The Reserves of Vitamins A and D in Some Cartilaginous Fish—

It has been stated for some time that certain liver oils of cartilaginous fish are antirachitic, particularly the liver oil of the ray. There is, of course, the consideration that cartilaginous fish are naturally rachitic, when comparisons are made between the calcification and the phosphate content of these fish with the bony fish, although in America, Bodanski and Bakwin did not find any difference in proportion of phosphate in the tissues of the two kinds of fish.

This investigation has been made on vitamins A and D in the liver oil of three varieties of cartilaginous fish: *Centrina vulpecula*, Rondelet, *Scymnus Lichia* Muller et Henlé, and *Raja batis* Linné. These oils prepared respectively in 1924, 1925, and 1926, showed marked differences in gravity, saponification values, iodine number, and fatty acids, also in unsaponifiable material.

White rats were used for the biological studies and the rachitic and growth values were compared with a good commercial cod liver oil prepared in 1928. Assuming a basis of 100 for the cod liver oil, the following values were obtained for vitamins A and D in these species:

	<i>Scymnus Lichia</i>	<i>Centrina vulpecula</i>	<i>Raja batis</i>
Vitamin A..	90	40	30
Vitamin D..	40	35	25

While a slight correction should possibly be made on account of their age, the antirachitic value of these oils is greater than that of one bony fish (*Merlucius Merluccius* Linné) examined previously. It appears that cartilaginous fish can store appreciable amounts of vitamins A and D in the

liver which does not have any influence on the skeleton.

Formation of some bony tissue in these fish such as teeth and dermal plates indicates that they are capable of elaborating some tissue with normal mineral content.—Amile Andre and Raoul Lecoq, *Compt. rend. Acad. d. sc.*, 194:912 (Mar. 7), 1932.

**The Vitamin D Content of Red Palm Oil**—The flesh or pericarp of the fruit of the oil palm, *Elaeis guineensis*, contains about 60 per cent, by weight, of red palm oil. This oil is known to be a good source of vitamin A. Four samples of red palm oil were tested for their vitamin potency on albino rats. The animals were fed Steenbock and Black's rachitogenic diets and the daily dose of oil necessary to prevent the occurrence of rickets at the end of 35 days was determined. The richest of the oils contained less than one-thirtieth as much vitamin D as cod liver oil. Red palm oil is considered a good source of vitamin A to use when it is desired to limit the quantity of vitamin D in the diet.—William John Dann, *Biochem. J.*, 26:151, 1932.

**Vitamin A and Carotene. IX. Notes on the Conversion of Carotene to Vitamin A in the Cow**—The author concludes:

1. Although the body fat of the cow is normally characterized by the presence of small amounts of carotene, vitamin A as such is present in preponderating amounts both in the liver- and milk-fats. Since the cow is purely herbivorous this finding suggests that carotene undergoes the conversion to vitamin A previously demonstrated in the rat.

2. This conclusion is supported by the finding that the feeding of carotene, in the form

evaporation. Milk is capable of adequately supplying this fraction for optimum growth.

The amount necessary, while lower than that required for the antineuritic factor, is also fairly large, that is 17 to

20 c.c. (2.37 to 2.78 gm. solids). The question of the identity of this heat-stable factor with the antipellagra fraction is still unsettled.—Leo. T. Samuels and Fred C. Koch, *J. Nutrition*, 5:307 (May), 1932.

## CHILD HYGIENE

### PALAMA SETTLEMENT

A UNIQUE combination of medical, dental, nursing, recreational, and health educational activities for children is to be found at Palama Settlement, located in the most congested district of Honolulu.

This institution had its beginning as a social center under church auspices in 1896. An extension of the services of the Palama Chapel took place in 1906, at which time its name was changed to Palama Settlement. A gymnasium and a swimming pool were added to the plant. Interest in the prevention of tuberculosis opened a vista for a broad public health program, in which prenatal and child welfare conferences were developed. Free dental clinics were established, and school nursing was initiated. In 1925 Palama Settlement moved into more commodious quarters, provided with recreation rooms, gymnasium, and swimming pool, an entire building for medical and nursing services, and a separate building for dental clinics made possible through the Strong foundation.

The demands upon the settlement became so great that in 1929 its direction was placed in the hands of a full-time public health administrator. Since then the work has been fully coördinated with all the health activities in the community. This has been especially helpful in the child health field. Dr. Philip Platt, the director, says:

Palama has become an aggressive leader in public health and preventive medicine. Efficiency of its medical and dental work now grown to some 68,000 services yearly has greatly increased. Standards of its public health nursing service have become notably high, and the contribution of the recreation department has been expanded many fold. Public health education, through the medium of its new Tuberculosis Committee, has taken forward strides. The more fundamental factors involved in the prevention of the ill health and economic misery of the family are promoted through a mothers' health clinic. Venereal disease is being vigorously combated. Participation on a score of committees has enlarged Palama's contribution to the community's welfare.

The Settlement as a voluntary agency stands ready as always to assist the official governmental agencies in the adequate performance of their tasks. It seeks to return to the Territorial Board of Health those activities which rightly belong to the official agency, such as the venereal disease clinic. It would gladly transfer its medical outpatient department to the Queen's Hospital, with its excellent in-patient department, believing that the best medical service to poor and the best training of a hospital staff can be had only when out-patient and in-patient departments are brought together as equal units of a hospital center. These developments, however, seem far distant.

The immediate future of Palama lies along the lines of preventive medicine, health education and youth upbuilding. The preventability of many communicable diseases, and the spreading of knowledge as to how to prevent disease and keep well, will be stressed with ever increasing emphasis. Not only tuberculosis, but mental hygiene, heart disease, and cancer control, the prevention of blindness, accidents, and venereal disease must

increasingly occupy the energies of Palama Settlement. Delinquency, because the boy or girl has no normal satisfying outlets in organized recreation or creative interests, will be aggressively combated as they have in the past.

Every summer 60 boys, then 60 girls, spend 4 weeks each at Palama's Fresh Air Camp on windward Oahu. Total weight gained last year: 288 pounds; 5 times the normal gain per child.

#### PALAMA'S RECREATION ACTIVITIES

- 2,096 full memberships
- 2,234 use the children's playground
- 40 Palama and Community Clubs
- 26 leagues, 181 teams, 2,352 players
- 65 other teams played at Palama
- 1,161 physical examinations
- 1,997 children given physical education instruction during school hours
- 1,030 given swimming instruction
- 56 Juvenile Court boys supervised
- 2,644 used Recreation Camp at Waiialua.

In Honolulu a joint nursing service is maintained by Palama Settlement and the local Board of Health. A generalized nursing program is carried out effectively in 25 nursing districts. In 1931 the public health nurses assisted in the health examination of 5,701 school children and gave 833 group inspections and 18,903 routine treatments.

Palama's \$200,000 budget brings medical, dental, nursing, recreation, and health education to more than 50,000 individuals. City appropriations, Chamber of Commerce donations, United Welfare Fund contributions, private foundation funds and institutional receipts balance the budget. Health education is Palama's corner stone.—

*The Story of Palama Settlement, The Friend*, Apr., 1932, Honolulu, Hawaii.

#### Summer in Child Health Work—

The summer season offers an exceptional opportunity to strengthen and extend health work among children. Summer should be conducive to better health conditions. This is the season of lowest mortality in childhood, as a result of the intensive public health efforts of the last 25 years. It may, however, be

a time when latent defects manifest themselves and when the children are exposed to accidents and certain of the infections easily disseminated in camp life.

The opening of playgrounds, summer camps, and vacation centers gives the health authorities a chance to check on their sanitary conditions and to raise standards. For this purpose it is very helpful to create summer camp councils in the large cities. Some cities have devised score cards for camps, which have been placed in the hands of the camp director so that each item may be checked. This may then be evaluated by the local health department. The Cleveland Camp Council has used such a card with good effect for several years. The items appearing on this score card for camps are as follows:

#### SCORE CARD FOR CAMPS

##### *Health Standards:*

- Resident doctor or nurse
- Physical examination of all child campers
- Physical examination of camp staff
- Physical examination of food handlers, including Wassermann and typhoid test
- Hand washing always practised after leaving latrines, especially by food handlers
- Every child in camp vaccinated
- Counsellors refer to children's health cards in supervising activities
- Daily health inspection of children at camp
- Fresh vegetables and fruits served every day
- Milk served three times every day
- Individual drinking cups and towels for all
- Fly control in kitchen or dining room
- Mosquito control methods followed

##### *Safety Standards:*

- Water for drinking, washing, and cooking analyzed by city health department before opening of camp and every 2 weeks afterward
- Water used for swimming also analyzed by city before and during camp
- Use only Class I pasteurized milk, approved by city
- Safe refrigeration for perishable foods and milk
- Garbage kept in covered cans and disposed of daily

Swimming only under supervision of Red Cross examiner  
 "Buddy" system in force during swims  
 Life-savers have thorough knowledge of prone pressure method of artificial respiration  
 Swimming periods never sooner than 2 hours after meal  
 Boats safe and never overloaded  
 Immediate isolation of sickness cases—contagious or otherwise serious

*Equipment Standards:*

Well equipped dispensary for caring for injuries  
 Special room or tent equipped for isolation cases  
 Sanitary latrines and safe sewage disposal  
 Convenient hand washing facilities near latrines  
 Proper equipment to facilitate washing before each meal  
 Equipment for children to have one warm bath with soap weekly  
 Comfortable dining room with shelter against bad weather  
 Hot water and sanitary drying facilities for dishes  
 Adequate fire fighting equipment: extinguishers, pails, ropes, ladders, and hose  
 Comfortable sleeping quarters with adequate protection against weather  
 Single cots with clean mattress and bedding, and at least 24 feet of space for each camper.

Another opportunity for health work among children is the summer play schools which have been established as parts of teacher-training institutions. In these schools, medical examinations, health inspections, and a considerable amount of health education can be carried out through the daily routine. It is always possible to use the lunch period as a time in which to develop proper attitudes toward food, as well as the suitable selection of food. The parents themselves usually take a great interest in the play schools; accordingly, a coöperative arrangement can be established with the home.

A very successful summer health school program has been carried out by the Los Angeles County Health Department for several years. During this summer they will promote this project in coöperation with the summer session of the University of California at Los Angeles. Two informative articles have appeared recently in *Hygeia* outlining the practical aspects of coördinating the health activities of the summer play schools.—Summer Play Schools, *Hygeia*, 10, 6:555-558 (June), 1932.

## PUBLIC HEALTH NURSING\*

**The Canadians Survey Their Nursing Situation**—The united forces of the Canadian Medical Association and the Canadian Nurses' Association have during the past 2 years been making a study of the nursing situation in Canada which will probably lead to the revolution of the system of nurse education and the organization of nursing services in that country.

The Survey Committee consisted of 3 prominent physicians and 3 prominent nurses, and the director was Dr. A. M. Wier, Head of the Department of Education, University of British Columbia.

A 581-page report has been published rather as the beginning for thought and action on the part of physicians, nurses, and the general public than as the conclusion of the matter. Provincial and national associations are already studying the facts presented by the survey with so much interest that the committee is confident that when a later survey is made a much happier nursing situation will be found.

A quotation from the report:

The evidence of the survey is conclusive on many points. Among these are that schools for nurses are not financed and organized as schools; the selection of students, their number, the curriculum and the teaching methods are not governed by public needs; the so-called schools are graduating nurses in too large numbers for resident service in homes and hospitals rather than for the developing public health services which are crippled by a shortage of qualified nurses; some system differing from the present one of direct payment by the patient must be created to provide essential nursing care in illness as well as in health.

When one studies the information on personal backgrounds, intelligence quo-

tients, training, employment, salaries, and personal satisfactions in jobs revealed in this report, it is not difficult to understand why the public and the medical and nursing professions are dissatisfied with the nurses' place in the national life of Canada.

The questionnaires returned by 1,475 doctors showed that while there was a 34 per cent surplus of graduate nurses, there was an actual shortage of public health nurses. The Survey Committee suggested that an increase of 20 per cent in the number of public health nurses in Canada generally, and 40 per cent in the Maritime Provinces would mean an excellent investment of money. The committee recommended, however, that public health nurses must be carefully selected and trained to succeed, and proper coördination of their services to prevent overlapping should also be maintained.—Eunice H. Dyke, *The Survey of Nursing Education in Canada*, *Canad. Pub. Health J.*, XXIII, 4:195-197 (Apr.), 1932.

**Public Health Nursing in New York State**—The Division of Public Health Nursing of the New York State Department of Health was created by legislative act in 1913. In that year there were 135 public health nurses in upstate New York; now there are approximately 1,500. While these nurses may be called visiting nurses, school nurses, tuberculosis nurses, child hygiene nurses, etc., they are all classified as public health nurses.

The present staff of the division of public health nursing of the State Health Department consists of "a director, an assistant director, an extension secretary, with an assistant, in

\* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

charge of special training courses for nurses; an office and visiting nurse; 14 district supervisors, responsible to the division for standards and procedures and to their respective district state health officers for development of the local public health nursing program; and about 60 other public health nurses who work in the field to promote the interests of various divisions of the department."

The State Education Department now employs 2 state-wide supervisors of school nursing appointed from a civil service list.

Of the 1,500 public health nurses working in upstate New York about 60 per cent are paid entirely from public funds: 583 are paid by private or voluntary agencies, and about 200 more are supported partly by official and partly by unofficial agencies.

After getting this birdseye view of public health nursing in the state the following recommendations of the New York State Health Commission take on new interest:

That as there are developed through the state, county health departments, each with an adequate staff of public health nurses, a qualified supervising nurse be placed in each unit under the direction of the county health commissioner, who shall (a) be responsible for the work of staff nurses; (b) serve in an advisory capacity to and coördinate the work of all public health nurses in the county.

That the State Department of Health be given authority to develop a better qualified public health nursing personnel in the state through:

- a. Enforcement of qualifications outlined by the Public Health Council
- b. Extension of supervisory and advisory service to local nurses and services where local supervision is found to be inadequate
- c. Provision for more specialized supervision in mental hygiene, social hygiene, social service and nutrition
- d. Extension of the present program of staff education

That greater coördination of school nursing with the general nursing services of the state be developed through more adequate super-

vision of full- and part-time school nursing, and that additional school nursing be provided, particularly in rural and village areas.

That the State Department of Health endeavor to develop local public health nursing services on a county unit basis providing for:

- a. A state-wide program of generalized nursing, to include rural school nursing
- b. Competent county supervision
- c. State supervisory and consultant service where local supervision is inadequate and does not follow accepted standards of supervision

That the State Department of Health make a concerted effort to promote local public interest through community activities which tend to advance county nursing programs.

That the nursing staff of the State Department of Health be reorganized, reallocated and classified as general district supervisory nurses, consultant specializing nurses and field nurses, and that suitable qualifications be required and salaries paid commensurate with the duties of such positions.

That the Public Health Council increase the present required qualifications of public health nurses, both as to preliminary education and postgraduate training.—

Public Health Nursing in New York State, Reprint from the *Report of the New York State Health Commission*, 1932.

**Requirements for Effective Work in Mental Hygiene**—Mental hygiene is interested in insanity and mental defectiveness, in stimulating psychiatric research, and in promoting a healthy public attitude toward these afflictions. It is interested in twists and distortions of personality, behavior problems, and in the establishment of all kinds of clinics for their effective treatment. But mental hygiene must be broader than this even, and interest itself in the general enrichment of life for all.

People who come in close contact with their fellow men, particularly if they have some responsibility for their direction, like public health nurses, for instance, and social and court workers, are in the best position to help achieve these aims of mental hygiene. Misfit in this field, however, are not to

tolerated, and there are some requirements if one is to do effective work.

First one must have such a love for human nature that she will be fascinated by the study of its operations, and will want to gain an understanding of the individual so that she can be guide, philosopher, and friend. A public health nurse who wishes to do real mental hygiene work should constantly be asking herself about her clients: "What are the reasons lying back of this behavior? What are the cravings of this man's soul, and how is he satisfying them? Would I not act in exactly the same way if I were exposed to the same environment and had the same mental equipment, the same mental assets and liabilities?"

Then one has to be a student of human nature. There are two ways of gaining knowledge in this field: one is through books (three recommended are Strecker and Appel's *Discovering Ourselves*; Grove and Blanchard's *Mental Hygiene*; and Carl Menninger's *The Human Mind*), discussions, and lectures. The other way is through continual study of people. Be familiar with these phenomena of the unconscious mind: repression, sublimation, rationalization, etc. Remember that we cannot explain behavior, whether conscious or unconscious, particularly if it is complex, unless we go beneath the surface and study the subconscious motivations.

Be familiar with the departures from mental health. Know what the criteria for mental health are. Know when a person is slipping. One way is to observe how an individual satisfies his ego hunger, how he submerges his own self interests in community interests, the way in which he faces the facts of life, including himself. One unhealthy way of satisfying ego hunger is by antisocial conduct; another is by thrusting oneself forward through self

deception and delusions of importance when one fails to secure recognition through merit and achievement; another way is ruthlessly to dominate, not one's equals, but those in the home, the office, the factory, the store, who, because of their positions, cannot avoid the domination. "It is always unhealthy to dominate unless domination springs from superior ability and better background."

A healthy way to satisfy ego hunger is to project oneself into work and be satisfied if it wins approval.

With adults we can study motivations directly, but with children who have not yet reached the philosophic stage we must study the environment and the influences that affect their growth—their home, their school, their playground, their mother and father.

It is very important for mental hygiene workers to study themselves first of all, to become their own patterns of reaction. This will keep them from "high-hatting their clients," for as soon as the social worker has evaluated herself she becomes common clay with the whole group, and will find that she can take a lesson from the prostitute or thief.

Another suggestion is to sit in on the conferences in your mental health clinics and gain an insight into the work from the psychiatrists and psychologists. A mental health clinic that does not energize a whole community of nurses, social workers or physicians is not worth the money put into it.

One person who has a real insight into mental hygiene and can use it to improve the mental health of all around her is worth her weight in gold. The one priceless thing is personality.—C. M. Hincks, M.D., *Requirements for Effective Work in Mental Hygiene, Indiana Bull. of Charities and Correction*, 203:213-218 (Mar.), 1932.

## EDUCATION AND PUBLICITY\*

Health Education Institute, October, 1932—The first Institute on Health Education to be conducted by the Public Health Education Section will be held at Hotel Willard, Washington, D. C., October 22-24, 1932, immediately preceding the annual meeting of the A.P.H.A. which opens Monday, October 24. The official announcement says:

The purpose of the Institute is to provide instruction in the content and methodology of health education to a limited number of persons actively engaged in health education.

The students whom it is desired to attract to the Institute, may or may not have had training in health education in one or the other of the very few institutions where it is available. They may have had a little or considerable experience. They may devote all their time to this work or it may be merely one of several activities. In any event, health education is for them a major preoccupation and they must from time to time formulate programs of activities in health education and carry them through.

At the Annual Meetings of the American Public Health Association there gather a large number of experienced individuals from various divisions of the public health field. The Health Education Institute is scheduled in connection with the Annual Meeting so that advantage may be taken of their presence.

The staff of the Institute is as follows:

Iago Galdston, M.D., Director, Medical Information Bureau, Academy of Medicine, New York, N. Y.

Bertrand Brown, Milbank Memorial Fund, New York, N. Y.

Ewart G. Routzahn, Russell Sage Foundation, New York, N. Y.

Mary Swain Routzahn, Russell Sage Foundation, New York, N. Y.

Clara E. Turner, Massachusetts Institute of Technology, Cambridge, Mass.

\*There will be a supply of samples of printed material and of other things which concern health education, to be distributed at the Institute, 115 East 22d St., New York, N. Y.

W. W. Peter, M.D., Cleanliness Institute, New York, N. Y.

Ira V. Hiscock, Yale University, New Haven, Conn.

H. E. Kleinschmidt, M.D., National Tuberculosis Association, New York, N. Y.

George C. Ruhland, M.D., Commissioner of Health, Syracuse, N. Y.

W. W. Bauer, M.D., American Medical Association, Chicago, Ill.

Frank J. Osborne, Health Officer, East Orange, N. J.

Raymond S. Patterson, John Hancock Mutual Life Insurance Co., Boston, Mass.

Active health education workers in official departments of health—state, county and city—and in voluntary agencies are invited to enroll.

Health officers and directors of health organizations are urged to send to the Institute the individuals responsible for health education activities in their units.

Application for enrollment in the Institute should be made on the prescribed form attached to this prospectus.

The registration fee is \$5.00 and must accompany application. Payment of the fee entitles the student to all the privileges of the Institute and to private consultation with the instructors, if desired. Students, whether or not they are members of the American Public Health Association, will enjoy the special railroad rate of three-quarters of the regular round-trip fare.

Mail checks and applications to: American Public Health Association, 450 Seventh Ave., New York, N. Y.

### WHAT IS THE PROGRAM OF THE INSTITUTE?

Saturday, October 22, 9 A.M.-12:00 *Health Education Instruments*: Discussion of the instruments employed in Health Education: pamphlets, weekly and monthly publications and bulletins, charts, posters, health talks and radio talks; their special utility and their limitations. Discussion leader: Ewart G. Routzahn. Discussers: Bertrand Brown, W. W. Peter.

Saturday, October 22, 2:00 P.M.-5 P.M. *Sources of Information*: The responsibility of the health educator for the authenticity of his material. How to go about securing de-

pendable information to present on the items selected, to the indicated audiences, and through the preferred media. Tapping authoritative sources. The coöperation of the medical profession. Discussion leader: Ira V. Hiscock. Discussor: Clair E. Turner.

Sunday, October 23, 9:00 A.M.-12:00 *Building Programs*: How to formulate a program of health education suitable to the community. How to determine the allocation of staff, money and effort. This problem will be considered from the viewpoint of both the official agency, that is, the department of health, and of the voluntary agencies. Discussion leader: Frank J. Osborne. Discussers: Ira V. Hiscock, Raymond S. Patterson.

Monday, October 24, 9:00 A.M.-12:00 *Program Execution*: The avenues through which the program might be formulated: the population at large, special groups, schools, primary and secondary, teacher training organizations, work shops and work places, commercial organizations, etc. Discussion leaders: W. W. Bauer, George C. Ruhland, Evert G. Routzahn.

A question period will be arranged for at the end of each discussion, though the participants in the Institute will be privileged to interrupt the discussor with pertinent questions.

**We Make Mistakes**—We are so sure of it that all copy for this department of the JOURNAL is submitted in advance of publication to those who should know the facts. If we are slow in sending out the checking copy we discover an excess of errors too late for correction. Here are the latest examples:

Eastman Kodak Company wish you to understand that any Dr. Haggard talks mentioned in this department are out of print. Only copies of talks yet to be issued can be supplied upon request.

Committee on the Costs of Medical Care wishes it to be understood that among their *free* publications are abstracts only of the larger, fuller reports published by the University of Chicago Press.

*Infants' and Children's Department* is published at 1 E. 35 St., New York. This is the trade journal interested in

"baby weeks" and other health services offered by department stores.

B. R. Rickards of New York State Dept. of Health reports that the Wednesday broadcasts of the department are at 6:25 E.D.S.T. over WGY.

American Child Health Assn. wishes me to emphasize that the bibliographies and other publications mentioned as *free* are supplied thus only as single copies. Quantities for a school or association are sold at low rates.

Also the *Emergency Nutrition Special* and the *Child Health Bulletin* mentioned under "Depression" are out of print. The valuable statement by Dr. Sherman has been reprinted. *3 cents for single copies.* Address at 450 7th Ave., New York.

Dr. Huntington Williams of the Baltimore Health Department emphasizes the pitfalls in editorial condensation:

The weekly health talks are broadcast under the joint auspices of the Baltimore City Health Department and the Medical and Chirurgical Faculty of Maryland and are given over Station WBAL each Tuesday at 6:15 P.M. Beginning April 26 the talks will be at 5:15 P.M. or 6:15 P.M. daylight saving time.

**Come to Washington to Learn**—Some of the attractions at the October, 1932, meeting of the A.P.H.A. are set forth most eloquently by Program Chairman Raymond S. Patterson:

The clinic will be the method employed once more by the Health Education Section at the Washington Annual Meeting. A "clinic" has to be attended for the method does not lend itself to successful reporting. You can't *read* about the operation and its successful outcome, you must be present to *see* it.

There will be another old fashioned clinic on printed matter! S.R.O. (standing room only—to you). Brain children of several proud health workers will be subjected to treatment guaranteed to make the antivivisectionist's flesh creep. Dr. Klein-schmidt will be the cruel fiend in human form who will do most of the dissecting.

The very best in health broadcasts will come

to you "over the air"—offerings by Haggard, Bauer, Rice, *et al.* Then the critics will be merciless. You will leave that clinic cautious about rushing into that inviting field where angels fear to tread.

There will be more meetings, too, at which other health propaganda methods will be taken apart to "see what makes it tick." But these are reasons enough why you must plan now to come to Washington to learn.

#### "Health Plays for School Use"—

This is the title of a 4-page mimeographed pamphlet, with annotated lists of plays and books on the technic of expression. American Child Health Assn., 450 7th Ave., New York. *Single copy free.* From the introductory paragraphs we quote:

It is important, if the richness and depths of a child's imagination and emotional nature are to be permitted free expression in the interest of learning, that the lesson in play form be not only truly imaginative, but also that its factual content ring true, and that the action have, inherent in it, real dramatic possibilities.

In selecting the health plays here listed, an effort has been made to choose those most naturally childlike, most naturally dramatic.

Teachers should remember, however, that the richest vein of dramatic possibilities for learning always lies in the child himself—especially in the little child. His original dramatic expression, in words and action, of an idea that is clearly presented to him and that has become thoroughly familiar, will always have greater educational value than any dramatic activity prearranged for him by others.

**Broadcasting By Voluntary Organizations**—The United States Office of Education is collaborating with the National Advisory Council on Radio in Education in making a survey of the present and contemplated uses of radio broadcasting by voluntary organizations. The principal purpose of this study will be to make available present plans and practices as a means of promoting mutually helpful relations between broadcasting agencies and organizations with public service objectives.

All state and local associations making use of radio or planning to do so are invited to ask the Office of Education, Washington, for the report blank which contains but 5 questions to be answered.

#### The Health Evaluation of Advertising—A recent letter from a public school director of physical education:

I am giving a lecture to a group of elementary teachers on "The Evaluation of Health Through Advertising" and I would appreciate the fact if you could give me some help. The gist of the subject is to evaluate statements made by people who are advertising health products.

This request brought a variety of interesting information and suggestions. What interested me most were two lesson outlines from Mary P. Connolly, Detroit Department of Health, on "Evaluating Health Information" and "Patent Medicines." Each presented "Aim," "Subject Matter" and "Procedure." The "Aim" of the first lesson:

To develop ability to judge health information intelligently.

To develop an intelligently critical attitude toward health advice.

To realize the folly of believing in health racketeers.

What can be taught to adults and young people as to discrimination in favor of sound and against unsound advice?

**What You Would Like to See at Washington**—What kinds of health education materials and helps would you like to see at the Washington meeting of the A.P.H.A.?

Have you any contributions? Any ideas? Any desires?

We had collections of the following at Montreal: Summer warnings and advice, Winter warnings and advice, Health examinations, Diet and weight, Diphtheria, Cancer, Rural sanitation, Colds, and Children and schools.

Will you select the best on those topics you have ever issued and send, to bring the collections up to date?

Please select the better examples from all types of publicity and health educational material you have ever issued and send for a special display? Address: Washington Display, Evart G. Routzahn, Russell Sage Foundation, 130 East 22d St., New York.

#### A Suggestion and a Request—

That (1) so far as possible pamphlets which are sold shall carry the price (preferably on the cover page), and (2) that copies of pamphlets, reprints, reports and other material sent to editors and those who make up reference lists for publication be accompanied by a memorandum stating whether or not copies are available—free, for a specified amount of postage, or for a set price. A few correspondents follow this very helpful practice. Then neither editor nor reader need guess—or write extra letters of inquiry.

It is important in sending pamphlets and research reports to *Publishers' Weekly* that the price be noted on the front cover. Otherwise they will add "apply," which reduces the number of inquiries or makes extra correspondence necessary.

Don't "Condescend" to Your Audience—Evidently Heywood Broun has not seen all of the good writing that is being done on health topics. But there is enough of the other kind to warrant our quoting several paragraphs from the *New York World-Telegram* (June 4, 1932). We may wish to check up on what we say or write.

The New York Academy of Medicine gave a dinner the other night to the newspaper men, and we all made speeches. First, some doctor would get up to say how much he admired the standards and ethics of journalism, and then a reporter would reply by laying it on pretty thick about the physicians. I was not quite in accord with the spirit

of the evening, for it seems to me that the efforts to make your liver and mine good feature copy have not been altogether happy up till now. I used to be among those who urged the members of the medical profession to abandon their secrecy and come out into the open to tell us what they were all about. But by now I have begun to lean back to the old Victorian tradition of reticence for healers.

It is not impossible to present scientific subjects in a popular and accurate form, but at least it is difficult. And when a doctor begins to write for newspapers or magazines of general circulation he has a tendency to go James M. Barrie on his public. I wish these missionaries to the laymen would not condescend so confoundedly. I would much prefer to know nothing at all about my heart than have it told to me in the form of a bedtime story.

#### When Speaking About Cancer—

*Cancer Compend: A Handbook for Speakers*, by R. V. Brokaw, M.D., American Society for the Control of Cancer, 25 West 43d St., New York. 44 pp. Free. Includes: "Approach to the Subject," "Important Facts," "Special Questions," "Statistics," "Bibliography." It is dated. The bibliography gives number of pages, address and price of each book.

So much of the "Approach to the Subject" has a general bearing on the presentation of health topics that we quote it in full.

Public speaking ability is fundamental in the successful presentation of any subject to any audience. No amount of knowledge can compensate for the lack of clear thought and precise statement under such circumstances.

The acceptable presentation of a public lecture on cancer is especially difficult because of the extensiveness of the field, the complexity of the problem, the gravity of the situation and the prevalent dread of the disease.

Conceding the possession of fundamental facts by the speaker, the method of presentation is important. The talk should by all means be adapted to the audience. The style of delivery suitable for the women's club, for instance, will not do for a radio broadcast. Non-technical language should always be employed. Brevity in the more formal part of the talk is preferable. An opportunity to

ask questions is generally appreciated; and the resulting discussion is often the most profitable feature of the meeting.

Experience has demonstrated that the following admonitions may well be heeded:

It is not wise to underestimate the experience of your audience. They may not be familiar with your specialty, but in some fields they may excel you.

One should not assume an *ex cathedra* attitude in presenting his subject. Judgment is never infallible; there are no unalterable conclusions; and most people are quick to resent an undue manifestation of authority.

Sentimentality should be avoided. An emotional appeal rarely produces any lasting convictions or stimulates any effective action.

Exaggerated statements are unnecessary. The exact truth about cancer is sufficiently hopeful, and sufficiently hopeless, to satisfy any degree of optimism or pessimism.

The pessimistic aspect of the cancer situation should not be emphasized. Pessimism is strongly conducive to paralysis; and that in cancer is most unfortunate.

Statistics should not be presented without a reasonable degree of certainty as to their accuracy and source. Absolute accuracy in quoting individuals is very important.

Critical comments regarding differences of opinion or of practice among physicians may profitably be omitted. Desirable results are not obtained by the creation of distrust.

The direction of attention to your own ability is likely to be embarrassing. Your audience will question your motive; and your colleagues will resent the inference.

An exhibition of prejudice regarding the treatment of cancer is unwarranted. Surgery, X-rays and radium are equally effective in their respective fields.

The recital of the details of surgical operations and of similar procedures is very undesirable. Such descriptions create fear and serve no useful purpose.

**"Discrimination In Health Teaching"**—An address on this subject by W. P. Shepard, M.D., has this "Conclusion":

Thus I have attempted to show that the rapid development of the school health program, its worthwhileness, its inspiration and its large rewards, taken together with the comparative infancy of the public health movement, have combined, first, to create a very fine liaison between the teaching and medical professions, and second, a rather insistent demand by the teachers for more

facts and more results from the doctors. This pressure might conceivably result in misunderstanding between the professions with resultant loss of confidence by teachers in the whole health movement. This is a catastrophe which can be prevented if foreseen. Public health men and physicians are gradually understanding more clearly what the teacher wants and the importance of coöperation. We realize that only by having children taught health facts and how to apply these facts can we hope to put the discoveries of preventive medicine to their best use—the prolongation of life. This can only be done when the teacher appreciates her responsibility to exercise a fine discrimination in selecting the content of her courses. And such discrimination can only be effective when the teacher understands something of the scientific approach and method, the pitfalls of fallacious reasoning, the limitations of science, and the necessity of selecting her authorities carefully.

A paper to be added to the library of the health educator whether working among adults or children.—Reprint from *California Quarterly of Secondary Education*, Berkeley. Apr., 1932. Apply to the author, 600 Stockton St., San Francisco, Calif., or Metropolitan Life Insurance Co., New York. *Free*.

**Mental Hygiene for the Public**—"Future Public Education in Mental Hygiene," by Sanger Brown, II, in *Am. J. Psychiat.* (Jan., 1932), and *Psychiat. Quarterly* (Jan., 1932), favors widespread public education.

Dr. Brown's article deals with the possibilities of public education in the promotion of mental health on a basis analogous to the widespread educational work in those fields of public health that deal with the human body. He states that "the time is fast approaching when public education in mental hygiene will take on the importance and significance of the campaign against tuberculosis, cancer and other widespread physical disorders."

Further he continues, "While many people are already well informed on the subject, education in mental hygiene for the great mass of people is practically virgin soil. Through the processes of an educational campaign the important facts of mental hygiene will gradually filter through from the more enlightened to the less informed and will eventually reach the average man."

"While a good deal of the material of mental hygiene is theoretical and there are some controversial subjects which should be avoided, a great deal that is definite and clear has already been learned with reference to the nature, the causes, the treatment and prevention of mental diseases, and there are certain essentials of this knowledge which should be communicated to the public. The commoner forms of mental adjustments and conflicts which so many persons experience should be made clear. Such conditions, for example, as anxiety states, fears, depressions, emotional instability, mental exhaustion, irritability, extreme sensitiveness, undue aversions, and innumerable other minor mental ills are suitable subjects for public education."—Paul Komora.

## NEW

*The Health Bulletin*, Bureau of Health, Knoxville, Tenn.

*Mental Health Observer*, Missouri Society for Mental Hygiene, 613 Locust St., St. Louis.

*News-Letter*, American Assn. of Psychiatric Social Workers, 41 East 47th St., New York. Now a printed bulletin. \$1.00 a year.

New in its smaller page, and in being printed in large type on dull-finish paper, is *Birmingham's Health*, Jefferson County Board of Health, Birmingham, Ala.

## MAGAZINE ARTICLES

"Hay Fever and Sensitivity," by Morris Fishbein, M.D. *Saturday Evening Post*. May 21, 1932. Includes heredity's effect, hay fever calendar, effect of humidity.

"Keep a Health Diary," by C. Ward Crampton, M.D.; "Dry Skin and Oily," by H. R. Cades. *American Girl*, 670 Lexington Ave., New York. May, 1932. 15 cents.

"The Risks of Childbirth," by Louis I. Dublin. *Forum*. May, 1932. Reprint from Metropolitan Life Insurance Co., New York. Free.

"Take Your Medicine," by R. F. Wadsworth, M.D. *Collier's*. May 28,

1932. "There's a lot in a point of view," "symptoms are catching."

## ON THE JOB

A. W. Jones of the St. Louis Tuberculosis Society is now also secretary of the Missouri Society for Mental Hygiene.

Claude E. Towner, of Monongahela, Pa., formerly editor of the *Monongahela Daily Republican*, and a former member of the legislature, was recently appointed news director of the Pennsylvania State Dept. of Health. Mr. Towner will write for the newspapers about department activities. The weekly syndicated health and dental talks will continue to be prepared by the Bureau of Public Health Education.

## MOTION PICTURES

The Red Cross picture, "The Symbol of Mercy," has been reproduced in 16mm film for use on portable sound projectors.

An enthusiastic review of "Arrow-smith" as a movie appeared in *Everybody's Health*, St. Paul, March, 1932. "Arrowsmith Shows Thrilling Adventures of Medical Heroes." We have heard that the motion picture version of the novel is free of some elements objectionable to the medical profession.

"Why Willie Was Willing to Wash." National Motion Pictures Co., Indianapolis. "The story of a very dirty little boy who becomes willing to get familiar with soap and water only after he has been vividly shown the extreme importance of cleanliness to himself." 1,000 feet. 15 minutes. Also in 16mm at less than half the cost of 35mm.

## HOW IT IS DONE

"Mark Time" and "Ben Hustler" give some good advice to inspectors of roadside eating places. *Public Health News*, New Jersey Dept. of Health. April, 1932.

"Investment," a "weekly health message" of the Iowa State Dept. of Health, is a half-dozen paragraphs urging the worthwhileness of health activities.

Several appreciative letters from former patients are published in the 1931 report of the Saturday Hospital Society, Leicester, England.

"Child Health Teaching" was presented in a round table conference of State Tuberculosis and Public Health Committee, S.C.A.A., New York. The participants included 11 speakers, a chairman, a secretary, a staff assistant and two consultants.

Something of the variety and extent of "education and publicity" possible in a specialized field is revealed in the annual report of the Chicago Heart Assn., as noted in its *Bulletin*, 203 N. Wabash Ave., Jan.-June, 1932.

"Health Education" heads 10 references in "Bibliography on Education of the Negro," by Office of Education, Washington, covering Jan., 1928, to Dec., 1930. If ordered from Supt. of Documents send 10 cents.

"Carrying Forward a Nation-Wide Service," a booklet of National Organization for Public Health Nursing (450 7th Ave., New York) is an effective, straightforward statement of the field and the activities of the association. *Free.*

New posters are announced and local campaigns of education reported in *Occasional Bulletin*, Health and Cleanliness Council, 5 Tavistock Sq., London, W.C.1, England.

A large circle, "Analysis of Each Dollar Spent by Imperial County" makes very striking the excessive modesty of the county's health budget. In *Imperial County's Health*, mimeographed bulletin of County Health Dept., El Centro, Calif.

For the best editorials on the Christmas seal cash prizes amounting to

\$125.00 were awarded by the Ohio Public Health Assn., Columbus. For best editorial in a daily: to G. J. Kochenderfer, Mansfield *Journal*. For best editorial in a weekly: to W. O. Markham, Mineral City *Promoter*; for second best: to G. A. Kikendall, Cuyahoga Falls *Reporter*.

"Dental Hygiene" is the central theme for the Jan.-Feb., 1932, issue of *Commonhealth*, Massachusetts Dept. of Public Health. On 41 pages appear 23 short articles—problems, projects, experiences. Information as to addresses and prices for securing educational materials and professional reading is lacking in some cases. Likewise in the general "Book Notes" no price is given for the title likely to interest more readers than the two books which are priced. Two letters are necessary to order that book.

#### USING THE MIMEOGRAPH

A printed heading for top of first page is used for the mimeographed *Bulletin*, Bexar County Public Health Assn., San Antonio, Tex.

A mimeographed front page on heavy tinted paper gives distinction to the monthly *News Letter*, Michigan Public Health Assn., Lansing. The other pages are on ordinary mimeograph paper.

Orange bond paper, with printed heading and tail-piece, makes it easy to recognize the monthly issues of *News Letter* of Dutchess County Health Assn., Poughkeepsie, N. Y.

A letter-size, mimeographed sheet invited the "neighbors" of Maternity Center Assn. of Brooklyn to a baby "fashion show," plus an exhibit, a playlet and a cup of tea. Paper cost \$.59; 500 envelopes, \$2.00; postage, \$10.00; mimeographing done in the office; illustrations "sketched by young art student"; envelopes addressed by volunteers; total cost, \$12.59. A few copies *free*. Address: 42 Livingston St.

## BOOKS AND REPORTS

**Human Physiology**—By Percy Goldthwait Stiles. Philadelphia: Saunders, 1932. 448 pp. Price, \$2.25.

The sixth edition of Dr. Stiles' book meets the need of the high school and college student admirably. In the lower grades the student learns health precepts and rules. With adolescence comes an inquiring skepticism and a challenge of accepted beliefs. He begins to think thoughts of his own and needs the raw materials out of which pragmatic knowledge is made. Dr. Stiles's presentation not only arouses his interest in physiology *per se* but also leads the student to draw logical conclusions that have a bearing on his conduct and help him to form sound opinions about public health.

Physiology is based on physics and chemistry. Anatomical shapes, appearances and arrangements present no great difficulties to the student (nor do they interest him profoundly), but it is not easy for him to visualize molecules and forces and to grasp the transformation of energy by living tissue. The author is a master in explaining such intangibles relating to structure and function. He has an ingenious way of picturing concepts by the use of apt analogies. For example, why does the victim of an amputation describe minutely, pains and other feelings, which seem to come from the lost limb? The brain receiving afferent nerve impulses associated with sensory endings is like "The engineer of a steamboat (who) cannot tell whether his gong has been rung from the pilot house or some other station." Is alcohol a depressant or a stimulant? There are two ways of accounting for the increase of the speed of a train descending a grade; more power may have

been applied or the brakes may have been taken off. Alcohol takes off the cerebral brakes.

Throughout the book the author adheres closely to what is actually known. In discussing disputed subjects or unproved theories, he avoids making unequivocal statements. Excellent judgment is used in emphasizing the important and excluding the extraneous, although the appetite for more detail of certain subjects must surely be whetted.

The practical suggestions as to how the student may use his knowledge are to the point and convincing. An example is the short but excellent section on the fundamentals of sex hygiene. The style is direct, the sentences are short, the illustrations are well drawn and free from confusing detail.

H. E. KLEINSCHMIDT

**Health Horizons**—Compiled by Jean Broadhurst, Ph.D., and Marion Olive Lerrigo, Ph.D., under the direction of the Emma Dolfinger Memorial Committee. New York: Silver Burdett, 1931. 516 pp. Price, \$3.00.

*Health Horizons* is a generous grist for the mills of health education. It is a prolific source of information on an extensive variety of subjects, intimately and remotely related to the content of health education for all levels of school and university work. It is a beautiful memorial to Emma Dolfinger.

In format, type and texture this volume has an uncommon appeal. It is legible, readable and full of one-thousand-and-one things that teachers, health educators and physicians will find useful, instructive and interesting. It brings together within the covers of a single volume a vast number of essential

facts gathered from the history of science, the laboratory, the clinic and the public health field. Each paragraph is succinct, terse, and to each are attached the essential reference facts, so that where there is need, one may go back to the original contribution for a more detailed statement.

The chapter heads are appealing and provocative. There are such interesting titles as "The Use of Milk Through Sixty Centuries," "Milk and Long Life," "The Useful Soy Bean," "Plant Malnutrition," "Pulling Teeth With Ashes of Ants," "Experiments With A Willow Tree," "George Washington's Dentist," "Commerce and Epidemics."

The material is divided into 23 sections in which are included all phases of individual and community health. There is a most laudable absence of anything suggesting self diagnosis and self treatment. The book contains an intelligently selected bibliography and a detailed index.

*Health Horizons* merits unconditional endorsement. It should be in the personal library of every health counsellor and health instructor, and in every hygiene class room. IAGO GALDSTON

**Influence of Social and Economic Factors on the Health of the School Child—By Raymond Franzen. Monograph IV of the School Health Research Series of the American Child Health Association. New York. 1932. 160 pp. Price, paper \$1.00, cloth \$1.25.**

Are we spreading our school health program too thin? Should we try to reach all economic levels or should we give more attention to the less privileged in the endeavor to wipe out some of the discrepancy in health opportunity existing between the extremes of economic levels? If so, what activities are appropriate for the different groups? These are questions that run through one's mind on perusing this book.

At a time when economic conditions are subnormal, a work of this kind is particularly appropriate. Municipal economics are threatening a reduced expenditure for health activities. Where shall the paring be done? What activities shall be curtailed? Although this book does not answer these specific problems, some of its findings should be helpful in the making of administrative adjustments. It shows what is not so surprising, and yet what we are so apt to forget, namely, that as compared with the school influence, social and economic forces have a preponderant influence in determining the state of health in school children. There are measurable evidences of the beneficial effects of our school health program efforts, to be sure, but relatively they are small.

The process of untangling the social and economic influences on health in order to identify the specific end result of a specific educational or corrective program, is a very difficult and complex affair. The analytical steps portrayed in this book take account of the intricacies involved and, though unfamiliar to most of us, yet we can appreciate the reasons for this care.

Have we not been undertaking social and health studies in the past in entirely too casual a manner? In this book we begin to see a new and distinct field developing—the field of biometrics, or the application of precise quantitative measurement to human affairs. We suspect that if it is given sympathetic and kindly consideration during its early developmental stage, a powerful ally to public health effort is in the making.

A few illustrations of the detailed findings reported follow. Health knowledge of 5th and 6th grade pupils is very largely determined by intelligence. The brighter children stand higher regardless of school health training. Scores on health education tests do not reveal success in health teaching until allowance has been made for the intelligence of

the child. The children of the better-to-do families have their hearing difficulties more adequately taken care of. Visual acuity, on the other hand, is no respecter of pocketbooks. Apparently there are no economic distinctions between schools either in the occurrence of vision defects or in their correction. Teeth are better cared for in families that can afford to pay for this service. But even a stronger influence is the type of home care as represented by what may be called cultural status. In children where families show a very small degree of absorption into American life—a very small frequency of intermarriages with American born mates—there are 3 times as many first molars missing as in children where parents are of those nativity stocks which most readily intermarry with the American born.

Group differences in children in the matter of nutritional status are almost entirely accounted for by social and economic influences. School health programs show no measurable influence on nutritional status over and above these socio-economic influences.

These are some of the points brought out in this fourth Monograph. A fifth volume promised later in the year, is to be devoted to an evaluation of school health practices. HENRY F. VAUGHAN

**Man and Medicine. An Introduction to Medical Knowledge—By Dr. Henry E. Sigerist.** New York: W. W. Norton & Co., Inc., 1932. 340 pp. Price, \$4.00.

Evidently the itch for informing the public concerning medical matters, which has been so apparent in America for several years, has passed on to Europe—but what a difference there is between this book and the usual grind which is turned out by American authors! Dr. Sigerist has succeeded to the chair held for so many years by Sudhoff, the acknowledged world-dean of professors of History of Medicine.

His approach to the subject is entirely different from that of any other book with which we are acquainted, and so is his treatment: In his preface, he says, "This book is intended primarily to acquaint young people who have chosen to enter medicine with the nature of their studies and their future profession, to guide and help them through the intricacies of the material which lies before them." He is a believer in the historical method of teaching, and has selected his basic facts from history. Running through the book, there are both philosophical and religious strains, ending with a quotation from Nietzsche which might well, with the Hippocratic Oath, be required of all students for graduation.

The book begins with a foreword by Dr. William H. Welch, and we agree fully with his statement: "I know of no other work covering the same broad field . . . So simple, straightforward, and devoid of unnecessary technicalities in the manner of exposition that the interest of the general reader cannot fail to be aroused." In fact, it has not been our good fortune to meet with any other book which is so interestingly written and contains so much material of value to students of medicine, or those who are considering the study. Indeed, it would be well if the public could be induced to read this book so that the attitude and ideals of the profession of medicine might be better understood.

MAZYCK P. RAVENEL

**League of Nations Health Organization Report of the Laboratory Conference on the Serodiagnosis of Syphilis Convened at Montevideo by the Institute for the Prevention of Syphilis of Uruguay September 15-26, 1930).** Boston: World Peace Foundation, 1931. 131 pp. \$.80.

The organization of the conference corresponded in principle to those pre-

viously held in Copenhagen. Specimens collected from patients who had been carefully studied were designated by serial numbers only and given to the serologists who participated. The results obtained with eight methods which employed complement fixation and four flocculation tests were compared. The findings corresponded to those secured at the Conference held in Copenhagen in 1928. The best flocculation tests proved more satisfactory than any of the complement-fixation tests with which they were compared.

The majority of serologists taking part in the Montevideo Conference agreed that, in the hands of Kahn himself, the Kahn "standard" test, which (as was the case also at the Copenhagen Conference) proved to be absolutely specific and extremely sensitive, was the best of those demonstrated at the Conference. Müller's clotting test (modification II) and Kahn's "presumptive" test (this latter test being specially designed for the control of syphilis in course of treatment) both gave a greater number of positive reactions with syphilitic material than did the Kahn "standard" test, but also two and three nonspecific reactions respectively.

Three out of the seven modifications of the B.-W method which were compared (Sordelli, Wyler, Scaltritti-Cassiniga) gave absolutely specific results, but a smaller number of positive results with syphilitic material than did the precipitation methods mentioned above. Other modifications of the B.-W method, without giving particularly sensitive results with syphilitic material, gave from 6 to 13.9 per cent nonspecific reactions.

In view of these findings, the employment of two different diagnostic methods simultaneously was recommended.

The sensitive methods for complement-fixation used in North America were not employed at the conference. Certain of these complement-fixation tests have been shown by the coöperative studies made from 1925 to 1930 for the Committee on Standard Methods of the Laboratory Section of the American Public Health Association (*Am. J. Syph.*, 1927, 1929, and 1930) to be slightly more sensitive and no less specific in their action than the floccu-

lation tests, including those of Kahn, Müller, and Meinicke, with which they were compared. RUTH GILBERT

### Noise and Vibration Engineering—

*By Stephen E. Slocum, Ph.D. New York: Van Nostrand, 1931. 171 pp. Price, \$2.75.*

This book presents valuable quantitative data upon the sources of noise and vibration and should be of distinct value to engineers and architects confronted with problems of vibration and noise prevention.

Vibrations with frequencies less than 15 per second are felt as tremors, whereas, vibrations with frequencies between 15 and 30 per second are heard as low rumbling noises. Musical notes and ordinary noise have frequencies between 30 and 15,000 to 30,000 per second.

The prevention of vibration is a problem of structural dynamics, wherein critical speeds of structures likely to be the source of vibration are avoided, or where vibration dampers or insulators are provided to change the continuity of vibrating structures. Thus the use of sheets of cork, lead, and asbestos pads at the foot of building columns results in damping of the vibrations of foundations before they are transmitted to the main structure, or similar insulators may be placed between separate units of structures.

The book deals first with transmission of elastic ground waves, and briefly reviews geophysical investigation of underground conditions by the use of seismographs. The properties of vibration dampers and insulators are then considered. Corkboard, hair felt, rubber, asphalt, lead, asbestos, sand and gravel are considered as vibration dampers or insulators. The results of a quantitative study of these materials are presented, and the actual practice in the insulation of tall buildings against transmission vibration is reviewed, with

special reference to the Grand Central Terminal in New York and the new Pennsylvania Railroad Station in Philadelphia, Pa.

The problem of preventing vibration and noise due to street traffic is considered in a separate chapter. The importance of smooth pavement and the possibility of insulating monolithic pavement structures from buildings are emphasized. Note is also made of the very material reduction in street noise resulting from improvement in the design of vehicles, track structures, etc.

Noises and vibrations are greatly intensified in enclosed subways. Experience with this subject in New York, Boston, Philadelphia, and London is reviewed, and the conclusion is drawn that the prevention of undue noise in subways requires careful consideration of practically all details involved in construction and operation of such structures. It is possible to line subways with sound absorbing material and thereby greatly reduce noise by damping reverberations. Improvements in track structures and rolling stock also are fruitful fields of development.

The economic aspect of noise abatement is considered. Although no precise information is presented relative to damages to structures due to vibration, or relative to the economic loss resulting from the nervous strain of those exposed to noise, nevertheless, the data presented indicate the seriousness of noise in urban communities and the necessity of active steps being taken to minimize vibration and noise. In general, the varied and complex subject of the control of noise in communities is shown to justify the creation of noise abatement commissions acting under local ordinances. The book concludes with a chapter on the mathematics of vibrating structures. A 9-page bibliography is appended.

This timely book is of chief interest to architects, and mechanical and civil

engineers. The sanitary engineer and other public health worker interested in the control of the environment, however, will find much of interest in the book. The author does not attempt to give data relative to the public health importance of community noise, although the nervous strain resulting from exposure to noise is indicated by quotation from literature. One gathers the impression, however, that the problem of eliminating unnecessary noise and vibration is of vast magnitude, requiring the coöperation of everyone acting under the guidance of noise abatement commissions, rather than municipal health departments.

CHARLES R. COX

### Social Problems and Social Planning

—By Cecil Clare North, Ph.D. *New York: McGraw-Hill, 1932. 409 pp. Price, \$3.50.*

This book presents a connected sociological approach to social problems. It shows the relation of essential sociological theory to the situations out of which social problems arise and to the procedure that is involved in dealing with such problems.

Following a somewhat philosophical discussion of human needs, attitudes, values, and culture, a chapter is devoted to the question of "Making up the Social Deficit." Activities concerned with the relief of suffering are classified under 4 divisions: the care of the economically dependent; the care of the handicapped and those unable to secure medical attention for themselves; the treatment of the delinquent; the amelioration of the living and working conditions of those who are lacking in adequate social protection or social opportunities. Social case work is defined as the study of the causes for the social difficulties that a person or a family may have, and the provision of a treatment designed to remove those causes and restore the person to normal social relations.

Various references are made to the relation of public health and social work and considerable space is given to the care of the sick poor. It is stated that the healing of the bodies of the poor has been done in a much more scientific manner than has the cure of their social difficulties. On the whole, the discussion of the medical care of indigent cases is presented in fully as favorable a light as the situation throughout the country warrants. In considering the subject of population and the shaping of population policies, the discussion of arguments against birth control concludes as follows:

The most that such efforts can accomplish is to retard the dissemination of information, and prevent the practice of contraception from securing the benefits of competent medical supervision which could be more easily accomplished if legal barriers did not exist.

Chapters on Fitting Government to Changing Needs, and Goals of Social Reconstruction are among the stimulating contributions. In view of the close relationship of constructive social service and public health work, and in view of the rapidly accumulating knowledge regarding fruitful lines of endeavor in both of these fields, this volume should prove interesting and helpful to many health workers as well as to the social work group for whom it was primarily designed.

IRA V. HISCOCK

Methoden der individuellen Auslese für gewerbliche Berufe—By *Theo-hald Fürst*—in *Abderhalden Hand-buch der biologischen Arbeits-methoden*—Berlin: Urban & Schwarzenberg, 1931. Abt. IV, Teil 16, Heft 1, Lieferung 371. 288 pp. Price, 15.50 marks.

This treatise on the methods of individual selection for industrial vocations falls into the field of industrial medicine as outlined at the International Conference at Lyons, France, in 1929. As defined by the author, this medical dis-

cipline is concerned with the medical selection of the individual worker and the estimation of his performance, capacity, and competitive limitations in the labor market; with the determination and estimation of industrial hazards; the medical consideration and supervision of these hazards; the hygienic supervision and sanitation of factories and industrial processes; the statistical analysis of the biological effects of industrial life upon the workers; and the experimentation necessary for the medical understanding of the materials of industry and the mechanism of industrial hazards. This section is concerned primarily only with the methods of selecting laborers, in the light of these other aspects of industrial medicine.

Of special value are the detailed blanks used in the study of the young worker. These make use not only of formal school records, but require quite a detailed analysis of personal qualities and behavior during the years of school life. Stress is laid on the physical, physiological, mental, and emotional traits which are indicative of departures from the norm, especially at adolescence. The constitution or hereditary complex is studied with reference to the detection of diathesis or of tendencies to particular types of disease, not only in the individual, but also in his parents.

The procedures in physical measurement, in examination of glandular development, posture, muscular development, respiratory function, heart and circulation, blood, nervous system, skin, and sense organs are given in detail and the significance of the divergences are noted. The work is well illustrated and the procedures are described with full detail. They are indicative of the great advance which industrial medicine has made in Germany in recent years. The work here outlined is basic in all preventive measures for the reduction of industrial hazards, in the proper placement of the individual worker, in his

stration; then a chapter devoted to contrasting and evaluating the four demonstrations; then a chapter each on "Physicians and the Demonstrations" and "The Demonstrations and Public Opinion"; ending up with an appendix outlining the program followed and a complete bibliography dealing with them. An interesting part of the book is a foreword by Barry C. Smith, General Director of the Commonwealth Fund.

At the very beginning of his discussion, the author has started off on the right foot in his statement concerning: "The modern child health program which has *contributed* to the phenomenal reductions in infant and child mortality of the last twenty-five years" (*italics are mine*). This moderation of statement is as unusual as it is refreshing in public health literature. Even the confirmed skeptic—of whom there are too few, in public health—would not take exception to such restrained language as this: "there is evidence, then, that measurable advantage to individual mothers and children followed health department service; and that the general effect of the demonstrations was to reduce infant and child mortality in the community as a whole." Mr. Dinwiddie has wisely avoided the meticulous inaccuracy of interpreting the drop in death rate in terms of dollars and cents.

The chapter entitled "Physicians" is especially to be commended to both practising physician and public health worker. The ten statements on pages 43 and 44 offered as "reasonably fixed premises for any permanently successful community program of preventive medicine and public health" are worthy of more than casual reading. Some exception might properly be taken to certain aspects of number 9. On the other hand, items 5 and 6 set forth the plain facts when they state that practising physicians are largely unprepared to guide the public in the field of preven-

tive medicine, and the public is largely unready to demand or pay for such guidance. It is the fashion in some quarters just now to emphasize the physician's unreadiness in contrast to the supposed eagerness of the public to receive instruction in hygiene. Experienced sanitarians know that it is a case of six of one and half a dozen of the other. Very few people are as yet willing to pay for hygienic advice; they often will not bother to avail themselves of it even if offered without charge.

No one interested in child health should fail to sample this meaty little book.

MERRILL E. CHAMPION

*Methoden der Arbeitsmedizin. Klinische Untersuchungen*—By Franz Koelsch—in Abderhalden Handbuch der biologischen Arbeitsmethoden, Abt. IV, Angewandte chemische und physikalische Methoden, Teil 16, Heft 2, pp. 289–496. Berufliche Krankheits- und Sterblichkeitsstatistik. *Ibid.*, pp. 497–518. *The two in Lieferung 376.* Berlin: Urban & Schwarzenberg, 1932. Price, 12.50 marks.

This part of Professor Abderhalden's great handbook of biological methods is a part of the section devoted to industrial medicine, and Lieferung 376 contains Dr. Koelsch's papers on clinical methods and morbidity and mortality statistics. The first of these contributions deals with the instrumental equipment for investigations in occupational selection, physiological and psychological, and for the study of fatigue. This is followed by a long account of investigations on the causes of industrial diseases such as aëraemia of compressed air workers, joint necrosis of phosphorus workers, silicosis of stone workers, etc., and an interesting list of investigations in progress arising from legislation dealing with hazards in new fields in the chemical industries, and periodic exam-

inations in older and better known hazards.

The second section treats of the pathology of the organ systems, especially of the skin and nails, as affected by industrial materials, manipulative processes, temperatures, electric current, X-ray, chronic eczemas due to galvanizing, exotic woods, chemicals which may incite cancer, etc. Discussion follows of the effects of pneumatic tools on the muscular and skeletal systems; of abnormal temperatures, gases, and dusts on the lungs; of certain chemicals on the digestive and urinary systems; of organic and inorganic poisons on the

central and peripheral nervous systems; and of certain employments on the sense organs. Nearly a hundred pages are devoted to industrial poisons, and their effects on the body, especially the new hazards arising from new products of the chemical industries. A fourth section deals with communicable disease fostered by industry, such as anthrax, foot and mouth disease, and hookworm. A brief account, with illustrative tables, is given to aims, methods, and fallacies of morbidity and mortality statistics as related to industrial medicine and to occupational diseases.

CHARLES A. KOFOID

## A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

**Diphtheria Death Rates**—This annual tabulation of diphtheria mortality in our great cities reveals a continuation of the marked decline. Deaths in 1931 were only half the number reported in 1929.

ANON. *Diphtheria Mortality in Large Cities of the United States in 1931*. J. A. M. A. 98, 19:1644 (May 7), 1932.

**When to Immunize**—In children under 3 months, about one-third of all diphtheria immunizations are failures; under 9 months one-fourth failed to respond. Between 2 years and 4, 5 per cent were failures. Under 9 months of age a preliminary Schick test should be given. These conclusions are numbered among many interesting observations.

BLUM, J. *Age Factor in Active Immunization of Infants Against Diphtheria*. J. A. M. A. 98, 19:1627 (May 7), 1932.

**Prohibition and Alcoholism**—"Prohibition" has not prohibited a notable increase, since 1920, in the number of persons who misuse alcohol to such an extent that they become mentally diseased: 1920 being the dividing

line in "before and after" drinking data.

BROWN, F. W. *Alcoholic Mental Disease Before and After Prohibition*. J. Am. Stat. Assn. 27, 177A:175 (Mar.), 1932.

**The Truth About Bran**—So prolific has been the pseudoscientific propaganda about bran, and so sour the counter blasts that this effort to get down to a dispassionate study is refreshing. It seems that bran's value lies only in its fiber content, but as healthy persons need 100 mg. or more of fiber per kg. of body weight each day, bran has its place as a source of supply.

COWGILL, G. R. and ANDERSON, W. E. *Laxative Effects of Wheat Bran and "Washed Bran" in Healthy Men*. J. A. M. A. 98, 22:1867 (May 28), 1932.

**Health Administration and the Care of the Sick**—After commenting on local health services in Boston, the author raises the issue of the medical care of the sick as a function of public health administration. Some practical details involved in the problem are suggested, and though no definite solu-

tion is proposed, the picture that is raised should prove potent to provoke discussion.

DUBLIN, L. I. The Coördination of a Community's Health Services. *New Eng. J. Med.* 206, 18:938 (May 5), 1932.

**Vitamin D Values in Irradiated Foods**—Of the common foods comprising the child's dietary, concludes the author of this excellent summary, milk, both liquid and dry, has thus far proved the most successful medium for irradiation: cereals and vegetables are unimportant sources of vitamin D. This will grieve the advertisers.

KOCH, E. M. Irradiated Foods. *Pub. Health Nurs.* 24, 5:263 (May), 1932.

**Cancer Prevention Propaganda**—"The giraffe has a long oesophagus, but does not have cancer there because he uses simple food and swallows slowly. . . . The domestic cow is milked and 'stripped' every morning and evening and no one ever hears of cancer of the udder of a cow. . . ." You may write your own annotation to this.

McCULLOUGH, J. W. S. Cancer at Home and Abroad. *Canad. Pub. Health J.* 23, 5:203 (May), 1932.

**Maternal Death Statistics**—"Vital statistics as compiled by the public health authorities cannot be used as a measure of the quality of maternity care." That this conclusion is correct those who read this excellent discussion will agree and perhaps thereafter some will hesitate to rush in where statistician-angels fear to tread.

MILLER, J. R. Can Vital Statistics Be Used to Measure Quality of Maternity Care? *New Eng. J. Med.* 206, 19:999 (May 12), 1932.

**Private Practice and Preventive Medicine**—The neglect of the sick cannot continue, for opinion demands adequate care for all. For most sick persons care must be provided by society. On these postulates is based the

author's discussion of the relationship of general practice to the preventive medical program here and abroad.

NEWSHOLME, A. The Relationship of the Private Medical Practitioner to Preventive Medicine. *J. A. M. A.* 98, 20:1739 (May 14), 1932.

**Streptococcal Disease Effects and Causes**—Three characteristics of the pathogenicity of hemolytic streptococci (rash producing, pyogenic, and invasive) vary from case to case. Host defence and cite of conflict also vary. These differences account for the variety of pathological patterns of human streptococcal disease, concludes the author. That seems reasonable.

OKELL, C. C. Haemolytic Streptococci in Infective Disease. *Lancet* 222, 5667-69:762 (Apr. 9-23), 1932.

**Preschool Child Posture**—In this excellent discussion of the posture of the toddler, the futility of attempting to apply grown-up standards to this age group is wisely emphasized.

PHILLIPS, W. M. The Posture of the Preschool Child. *Pub. Health Nurs.* 24, 5:236 (May), 1932.

**Standardizing Streptococcus Antitoxins**—A practical laboratory animal method of measuring the potency of scarlet fever streptococcus toxins and antitoxins is described. The end results are superior to similar tests on human subjects. Incidentally, the differences in neutralizing value of the different products is discussed.

VELDEE, M. V. The Standardization of Scarlet Fever Streptococcus Antitoxins. *Pub. Health Rep.* 47, 19:1043 (May 6), 1932.

**Some Social Philosophy**—Food for thought for the socially minded health worker, and for those too who like this annotator would have to answer in the negative such questions as these propounded by the author: "Or did it ever occur to you to consider why there

## NEWS FROM THE FIELD

### STATE CHARITIES AID SIXTY YEARS OLD

THE State Charities Aid Association of New York celebrated its 60th birthday on May 11, 1932. The original purposes for which the Association was founded in 1872 still hold: To promote an active interest in public charitable institutions in the State of New York, in order to improve the condition of their inmates, and to make more efficient the public relief system in the light of "the most enlightened views of Christianity, Science and Philanthropy."

### LOS ANGELES PUBLIC HEALTH EXHIBIT

THE first display of equipment, materials, methods and services for the furtherance of public health ever to be held on the Pacific Coast has been announced. This will be the Los Angeles County Public Health Exposition, to be conducted under the sponsorship of the Los Angeles County Tuberculosis and Health Association, and will be held from August 12 to 18, in the permanent buildings of the International Industrial Expositions, Limited.

### NEW YORK STATE SEWAGE WORKS MEETING

THE New York State Sewage Works Association held its Spring Meeting at Buffalo, N. Y., June 10 and 11. Important papers were presented by Clyde Potts, Harold J. Huber, Edmund B. Besselièvre, A. F. Dappert, C. C. Agar, Earle B. Phelps, K. A. Keirn, and others.

### GILMORE MEMORIAL FOUNDATION

TO perpetuate the memory of Eugene S. Gilmore, for 25 years Superin-

tendent of the Wesley Memorial Hospital, Chicago, the Eugene S. Gilmore Memorial Foundation has been created by his friends and associates. The Foundation will create a Fund, the income of which will be used in establishing scholarships for the graduates of Wesley Memorial Hospital School of Nursing.

### COURSES ON CHILD HYGIENE IN ITALY

THE National Children's Bureau of Italy has just issued a circular to its provincial branches ordering the establishment of popular courses on maternal and infant hygiene for girls between 16 and 18 years. The courses are to consist of practical and theoretical work and are to be given preferably in infant welfare institutions, for instance, day nurseries. The girls attending such courses will not be entitled to diplomas because these are issued only to graduates of special courses for the training of persons intending to take up maternal and infant welfare work as a profession.—*Maternità ed Infanzia*, Rome, Jan., 1932.

### MEDICAL COLLEGE OF VIRGINIA

THE Carnegie Corporation of New York has made an appropriation of \$10,000 toward the maintenance of the library of the Medical College of Virginia, which will be housed in a new building this summer. Adjoining the new library of the college, the Richmond Academy of Medicine has built its home and library, which will contain the famous Joseph L. Miller collection of rare first editions, engravings, silhouettes, medical curios, etc.

## FLORIDA PUBLIC HEALTH ASSOCIATION

THE Florida Public Health Association has become a member of the American Public Health Association, and is therefore now included among the Affiliated Societies with a representative in the Governing Council of the Association—this representative to be announced later.

The present officers of the Florida Public Health Association are as follows: President, Horatio Newton Parker; First Vice-President, Inez M. Nelson, R.N.; Second Vice-President, Rothwell Lefholz, M.D.; Secretary, Stewart G. Thompson, D.P.H.; and Treasurer, Stewart G. Thompson, D.P.H.

## GORGAS ESSAY CONTEST

HARRIET JONES, a high school junior in St. Agnes School, Albany, N. Y., was awarded the Henry L. Doherty Prize of \$500 for the winning essay on mosquitoes in the Fourth Annual Gorgas Memorial Essay Contest.

President Hoover, as Honorary President of the Institute, presented the award at the White House on June 9.

The subject of this year's contest was "Mosquitoes, Their Danger as a Menace to Health, and the Importance of Their Control." High school juniors and seniors from every state and the District of Columbia participated, and 15,000 manuscripts were submitted.

## MEDAL FOR DR. THEOBALD SMITH

THE Council of the Royal Society of Tropical Medicine and Hygiene of Great Britain, at its annual meeting, June 16, awarded the Manson Medal to Dr. Theobald Smith, of Princeton, N. J., director emeritus of the Department of Animal Pathology, Rockefeller Institute for Medical Research, New York, and formerly professor of comparative pathology, Harvard University.

## MEMORIAL TO C. HAMPSON JONES

A COMMITTEE has been formed to arrange for a memorial to Dr. C. Hampson Jones, Charter Fellow of the A.P.H.A., who died April 11, for many years Health Commissioner of Baltimore, with Dr. Huntington Williams, Director of Health, as chairman. The memorial will take the form of an oil portrait of Dr. Jones, to be placed in the Health Department offices.

## PERSONALS

SIR HENRY WELLCOME, LL.D., F.S.A., founder of The Wellcome Research Institution, has been elected Honorary Fellow of the Royal College of Surgeons of England. Sir Henry Wellcome is of American birth, and is well known for his world-wide scientific work and extensive pioneer researches in connection with tropical diseases, including the founding of The Wellcome Tropical Research Laboratories at Khartoum on the Upper Nile Regions of the Sudan, Africa. He is also a director of the Gorgas Memorial Institute, Washington, D. C., with its Tropical Research Laboratories at Panama.

DENNETT L. RICHARDSON, M.D., member A.P.H.A., formerly Superintendent and Resident Physician of the Providence City Hospital, now known as the Charles V. Chapin Hospital, was appointed Superintendent of Health of Providence, to fill Dr. Chapin's place.

MATHILDE S. KUHLMAN, R.N., Director of the Division of Public Health Nursing of the New York State Department of Health, died suddenly on May 30. Miss Kuhlman was a former president of the State Organization for Public Health Nursing, Fellow of the A.P.H.A., member of the American Nursing Association, National League of Nursing Education, and the Albany City Club.

## CONFERENCES

July 21-29, 100th Anniversary Meeting, British Medical Association, London.

July 25-30, Regional Conference of the World Federation of Education Associations, Honolulu, Hawaii.

August 12-18, Los Angeles County Public Health Exposition, Los Angeles, Calif.

September 6-9, International Union Against Tuberculosis, The Hague.

September 12-19, American Hospital Association, Detroit, Mich.

October 3-7, Twenty-first Annual Safety Congress and Exposition, Washington, D. C.

October 24-27, 61st Annual Meeting, American Public Health Association, Washington, D. C.

November 14-18, Tenth Annual Short School, Texas Public Health Association, Dallas, Tex.

## Some Epidemiological Aspects of Psittacosis\*

H. E. HASSELTINE, M.D., F.A.P.H.A.

*Senior Surgeon, U. S. Public Health Service, Washington, D. C.*

IN the winter of 1929-1930, the appearance of psittacosis in the United States and in various parts of the world drew the attention of health authorities to this disease. Until that outbreak it was considered as a disease of birds of the parrot family that occasionally affected man and was supposedly caused by the *B. psittacosis* of Nocard, a member of the *Salmonella* group, practically identical with *S. aertrycke*.

With the recognition of a disease of human beings apparently due to association or contact with birds of the parrot family, many public health laboratories began work upon the affected birds to throw light upon the diagnosis of the condition. Many workers failed to cultivate *B. psittacosis* from any of the sick, or dead birds, while a few succeeded, obtaining it from a small proportion of the birds examined. However, it did not take long to ascertain that the infection was communicable from birds to laboratory workers.

At the National Institute of Health (then the Hygienic Laboratory) two persons assigned to the work on the disease became ill within a short time, one resulting fatally. A third worker who carried on the investigation for approximately 1 month escaped the infection. However, 9 other persons who had no direct connection with the work on psittacosis but whose duties required them to work in the same building developed the disease. At about the same time 2 workers in the Baltimore City Laboratory developed the disease, and 1 of these, Dr. William Royal Stokes, director of the laboratory, died.

---

\* Read at the Third Annual Meeting of the Western Branch American Public Health Association, at Denver, Colo., June 10, 1932.

Other cases occurred in the New York State Laboratory at Albany and in the New York City Laboratory.

Investigations carried out in Europe by Bedson, Western and Simpson, and in the United States by Krumweide, McGrath and Oldenbusch, and by Armstrong, McCoy and Branham, showed the disease was due to a filtrable virus. Krumweide, McGrath and Oldenbusch found that it could be transmitted to white mice. Studies of the pathology of the disease in birds by Levinthal in Germany, Lillie in the United States, and Coles in England showed lesions differing in some respects from those found in other conditions, particularly in that certain cells contained rickettsia-like bodies to which Lillie gave the name *Rickettsia psittaci*. Whether these bodies have a causal relationship to the disease, or appear as a result of the infection is not yet determined.

After the development of cases in their laboratory workers, the New York City Department of Health turned over its birds and experimental animals to the Rockefeller Institute of Medical Research, where investigations were continued under strict precautions to avoid laboratory infection; yet later on, 1 case developed in this laboratory. Continuing the work begun by Krumweide and his associates, Rivers and Berry were able to establish the infection in white mice, and later on in other laboratory animals. It was found that in mice the disease was far less dangerous for laboratory workers than when birds were used as experimental animals, and, therefore, cases of laboratory infection have been few since that fact became known. These workers also showed that if the virus is introduced into the nose or trachea of monkeys, the animals contract the disease and show pulmonary lesions resembling pneumonia. If the virus is injected intracerebrally the pulmonary lesions are not found though the animal develops a meningo-encephalitis. This finding suggests that most of the cases of psittacosis receive their infection through the respiratory tract. Armstrong reports that in the 1929-1930 outbreak there were 169 cases with 33 deaths in the United States. This outbreak was attributed to the importation of infected parrots, though occasionally human cases were found to be associated with parrakeets or canary birds.

Early in 1931, 5 cases with 2 deaths occurred in New York City that were traced to "love birds," a term that is frequently applied to parrakeets. These birds had been brought into the United States from Havana.

In October, 1931, another group of 3 cases, with 1 death, occurred in New York City. These cases were traced to shell parrakeets that

were obtained from San Francisco. Subsequently it was ascertained that at least a part of this shipment had been imported from the Orient. The diagnosis was established by laboratory tests upon mice.

Early in December, 1931, the California State Department of Public Health learned that 3 of 4 persons who had spent one day (November 27) at a certain home in Grass Valley, Calif., had been taken sick at approximately the same time. The fourth person sickened about a week later; all 4 died. Upon investigation it was found that a pair of shell parrakeets had recently been introduced into the household, the birds having been obtained from an itinerant vendor. One of the birds died a few days after it was acquired. The other bird, although apparently healthy, was subjected to laboratory examination and the presence of the virus of psittacosis was proved. Later similar findings were obtained from autopsy material from one of the human cases.

Subsequent investigations showed that itinerant bird vendors had visited various parts of the state and that in many families that had bought birds there had occurred peculiar cases of disease, some of which resulted fatally. One of these bird vendors had obtained at least a part of his parrakeets from the San Francisco dealers who had shipped the birds to New York City in September that resulted in the 3 cases of psittacosis in New York in October and November, mentioned above. It, therefore, seemed likely that most of the cases traced to birds sold by this vendor could be attributed to imported birds. However another California patient obtained parrakeets from another vendor whose source of supply was California bred birds. Further inquiry revealed a parrakeet breeding industry in California that is of considerable magnitude. Subsequent investigations have furnished ample evidence that some of these breeding establishments harbor birds that carry the virus of psittacosis. These investigations have also shown that many birds may act as apparently healthy carriers of the infection. The extent of the infection in these aviaries is not fully determined, but all indications suggest that it is sufficiently extensive to constitute a most perplexing problem.

From what has been related above, it seems apparent that we have in the United States a disease of birds that is highly communicable to man. The specific cause is a filtrable virus; the chief contributing cause is contact with infected birds or human cases of the disease, or their environment, either as a result of occupation, family association, or casual circumstances.

Since Armstrong collected data on the cases of the 1929-1930 outbreak, I have obtained information on 12 cases occurring in New

York and 43 cases occurring on the Pacific Coast, which is recorded here. Of the 43 cases occurring in California, laboratory examination of the suspected birds was made in 24 cases, of which 20 showed positive results, 1 negative, and 3 were incomplete at the time of compiling these figures.

#### INFORMATION COLLECTED ON 55 CASES

*Sex*—Of the 55 cases, 18 (32.73 per cent) were males, 37 (67.27 per cent) females. It is believed that the greater frequency in females is due to the fact that women spend a greater portion of their time in the home, usually care for the birds, and frequently handle them and teach them certain tricks, such as taking food from the mouth of the mistress, which result in closer contact with the birds. It is of interest to note that Barros reports an outbreak in Argentina where the birds were attended largely by men and cases of psittacosis were far more prevalent in males. We have no reason to believe that sex *per se* has any influence on the incidence of the disease in human beings.

*Age*—Armstrong found cases in all age groups, though more frequent in those between 20 and 70 years of age. The ages of the 55 cases under discussion are given in Table I.

TABLE I

Age Group	No. of Cases		No. of Deaths	
	Male	Female	Male	Female
10-19	0	1	0	0
20-29	1	1	0	0
30-39	3	7	2	0
40-49	9	13	2	0
50-59	1	10	1	5
60-69	3	3	2	1
70-79	1	2	0	0
	18	37	7	6

Armstrong calls attention to the fact that in his group of 167 cases there were no deaths below the age of 30, while approximately 24 per cent of those above 30 proved fatal.

*Occupation*—Any occupation that brings the individual into contact with birds of the parrot family may be considered as a contributing cause. The occupation that heads the list is that of housewife, and the explanation of this is given under the consideration of the sex distribution of cases. Three of the women in the group of 55 cases herein reported probably contracted the disease as a result of nursing human cases. One man worked in a pet shop that had infected birds. Fourteen were owners of parakeet breeding establishments. Eight of these aviaries showed positive results on examination of their birds; 1 gave negative results; and in 5 the laboratory tests were not made or had not been completed at the time of compilation of this report. Two cases, man and wife, owned an aviary of canaries which showed the infection present in 2 of 11 birds examined. One patient was a customs inspector whose duties required him to examine shipments of birds at their port of entry; another was a health official assigned to duty inspecting aviaries; another was a butler in a house

that harbored parrots; and another was a laboratory worker who obtained supposedly normal parrakeets for experimental use in studying a disease of parrot-like birds, other than psittacosis. His sputum, when inoculated into mice, showed that his illness was psittacosis and not the disease he was investigating.

*Seasonal prevalence*—The colder months of the year have thus far furnished the greater number of cases. Possibly the exceptionally cold winter in California has had a part in precipitating the outbreak of 1931-1932.

*Contact infection*—Although instances of the transmission of the infection from one human being to another are relatively few, the reporting of such cases has been sufficiently frequent to prove that the disease may be contracted in this manner. In a few instances all contact with birds of the parrot family has been excluded. Sturdee and Scott describe a case in a physician who attended a case of psittacosis. The patient went to the physician's office for consultation and did not see the physician again until 1 week later when the doctor was called to the patient's home to attend him. The bird that presumably infected the primary case had died 2 or 3 days before the physician made his first visit to the patient's home. Twenty-four days after the date of this first visit the physician became ill from psittacosis. Also a sister of the primary case came to nurse her brother, arriving at the home after the death of the parrot. Within 2 weeks she also became sick with psittacosis.

Armstrong reports 2 cases where persons nursing fatal cases of psittacosis contracted the disease, and in both instances the history of contact with birds of the parrot family was lacking.

One of the cases occurring in the California group was undoubtedly contracted while nursing a relative who died of the disease. The primary case, one of the group of 4 cases that brought the existence of psittacosis to the attention of the State Department of Public Health, received her infection at Grass Valley, Calif., on November 27, 1931. She was taken sick on December 6, 1931, after she had returned to her home, about 150 miles from the place she received the infection. When she became sick she summoned a niece to attend her in the capacity of a nurse. She nursed the patient from December 7 to December 12, on which date the patient was removed to a hospital where death occurred on December 18. On December 16 the niece was taken sick with symptoms of psittacosis. She recovered after an illness of about 3 weeks. In this instance the secondary case had not been within 150 miles of the birds that infected the primary case, and no history of contact with birds at any other place could be obtained.

Two other California cases are cited as illustrative of another group that is probably due to human transmission, though remote contact with birds cannot be absolutely excluded. Both were nurses who attended 2 cases of psittacosis in a family. The primary cases, man and wife, were taken sick on February 3 and February 5, respectively, and the man died on February 25. One nurse was taken sick on March 3, the other on March 10. This couple had about 25 parrakeets in a cage in their backyard. The nurses stated that they had never been near the cage nor in contact with the birds, though a blanket that was used to cover the cage had been thrown over a line in the yard and they had walked past this blanket.

An interesting addition to our knowledge of the disease was obtained from this group of birds. Three of the 25 birds became sick and died. Laboratory examination proved them to have had psittacosis. The remaining 22 birds, apparently well, were then sacrificed and each subjected to laboratory examination:

13 of the 22 were found to harbor the virus of psittacosis. In 3 other California cases possibility of infection from a human case was found though the secondary cases also gave a history of contact with infected birds.

While on the subject of transmission from man to man, it is desired to call attention to the fact that many of the instances where secondary cases have been found, the primary case has resulted fatally. Whether this means that the virus is more potent or that it is more effectively disseminated by the primary case, or that some unknown factor may have an influence, cannot be stated at this time. We do know that most of the cases develop a peculiar pneumonic lesion. While cough and expectoration are not prominent symptoms in the average case that ends in recovery, it frequently happens that in the late stages of a fatal case repeated efforts are made to clear the air passages of a thick tenacious sputum by coughing. This would greatly increase the possibility of dissemination of the disease by the droplet method.

#### CONTROL MEASURES

Psittacosis is a disease that affects man largely as a result of human fondness of pets. Rabies also qualifies in this class. In theory, both are easy to control, but our difficulties in controlling rabies warn us that psittacosis will also be a difficult problem. Fortunately, the psittacotic bird is not aggressive as is frequently the case with rabid animals.

The essence of the prevention of psittacosis lies in avoiding contact with birds of the parrot family. Thus far I have yet to find any argument that proves parrots or similar birds are a *necessity*. Neither have I found any one who can show that they fulfil any economic function. The parrot industry is founded upon the natural love of pets by human beings. To do away with pets it is necessary to change human nature.

Control measures therefore must be relied upon, and these divide themselves into two sub-heads, (1) restrictive measures, (2) educational measures.

Restrictive measures may be further subdivided into those applicable to importation of birds, and those applicable to domestic bred birds. Parrots and the larger birds of the parrot family do not breed in captivity to an extent that will make domestic raising of such birds profitable. On the other hand, parrakeets and love birds will breed readily in captivity in the United States, and a rapidly growing industry in breeding these birds has become established in Southern California.

The following measures are applicable to imported birds:

1. *Embargo*: This aims to exclude all birds specified in the embargo order. During the outbreak of psittacosis in 1929-1930 an embargo on parrots was made effective January 24, 1930. The

embargo did not apply to other birds of the parrot family as the outbreak of 1929-1930 seemed to be almost wholly due to infected parrots.

2. *Quarantine*: On October 21, 1930, this embargo requirement was modified so that parrots might be admitted if shipped under prescribed conditions and detained at the quarantine station at the port of arrival for 15 days, provided none of the birds showed signs of illness during the detention period. Other members of the parrot family were not subject to detention. This provision has been in effect for more than 18 months, and human cases of psittacosis tracing to parrots have been few, if any. On the other hand, numerous cases have been traced to other imported birds of the parrot family, and in February, 1932, the detention period was extended to cover all birds of the parrot family.

At about this time it was found that psittacosis was present in domestic parrakeet aviaries, so it has been difficult to say what has been the effect of this detention of imported birds since that time. Recent findings that apparently healthy birds may be carriers of the virus lessen the value of quarantine detention as a control measure.

3. *Import duty*: The customs duty on imported birds has been low. While an absolute embargo may work a hardship upon some scientific organizations that desire to import birds, as well as upon individuals desirous of having birds at any price, a high duty on psittacine birds would allow importation in such instances yet largely restrict commercial traffic in such birds.

Several control measures are applicable to birds bred in the United States and to establishments handling imported birds after arrival.

1. Every person or firm engaged in the breeding, buying, selling or exchanging of birds of the parrot family should be registered in the office of the proper health authorities.

2. Every person or firm engaged in any of these activities should be required to keep records whereby the tracing of infection may be facilitated. Such records should also include information as to cases of illness and death among birds in the establishment. Such records are always to be available to the health authorities.

3. The sanitation of aviaries and pet shops may be left to judgment of the local authorities, due attention being given to housing conditions for birds, particularly overcrowding, cleanliness and proper maintenance of the plant. The same conditions should be considered for shipments of birds while in transit.

4. Isolation of sick birds should be required and, if possible, laboratory examination of birds dying from disease, for evidence of psittacosis should be made.

5. If necessary absolute quarantine of an establishment may be invoked.

On a recent visit to California I visited several parrakeet breeding aviaries and learned that in nearly every brood of young parrakeets there are a varying number of "crawlers." A "crawler" is a young parrakeet that is too weak to fly when the bird leaves the nest. Such birds drop to the bottom of the cage and crawl about the floor for a time. Many of them die, but some gain sufficient strength to enable them to fly.

I also learned that such birds are often bought by bird vendors, particularly itinerant peddlers, at a very low price and notwithstanding the loss of a considerable number by death; the survivors are sold at a sufficient advance to make the transaction profitable.

In view of the prominent part played by parrakeets sold by peddlers in the California outbreak, and the frequent history of sickness and death of the birds acquired shortly after purchase, it occurred to me that possibly these weak birds or "crawlers" may actually be cases of psittacosis in birds. It is well known that the greatest mortality in aviaries is in the young birds, suggesting that possibly the older birds have had the disease and recovered. If such is the case, an effective control method might be found in requiring birds to be held until they have reached a certain age before they are disposed of by the breeders.

#### EDUCATIONAL MEASURES

These consist of the dissemination of information concerning psittacosis and how to avoid it. Emphasis should be laid upon the fact that if contact with birds of the parrot family be avoided, the danger of contracting the disease is greatly reduced. Those persons who will not avoid all contact with psittacine birds should be warned (1) of the dangers of psittacosis; (2) that it is more likely to appear in cold weather when the birds are kept within the home and in closer contact with human beings; (3) that recently acquired or young birds are more dangerous than birds that have been in the family for some time, *provided such birds have not been in contact with infected birds* (some of the cases of psittacosis discussed in this paper were contracted from birds that had been in the family for years, but had been taken to an infected bird shop for treatment or for boarding during the absence of the owner); (4) that the practice of feeding birds from the mouth, "kissing," etc., is extremely dangerous if the bird harbors the virus of psittacosis; (5) that any sickness in birds should be regarded as suspicious; (6) that cages should be kept clean, cleaning

being preferably done out of doors in the sunlight after the cage has been moistened to prevent the dissemination of dust.

Should a case of psittacosis occur in a member of the household it should be isolated and ordinary bedside prevention measures applicable to other infectious diseases should be practised, particularly the disinfection of sputum, the use of gauze in place of handkerchiefs, the gauze being burned after it has been used.

It is believed that the educational measures should be stressed since the American public knows little, if anything, concerning this dangerous and relatively highly contagious infection.

#### ACKNOWLEDGMENTS

Grateful acknowledgment of indebtedness to each of the following groups is hereby made, for information and data furnished: California State Department of Public Health; City Health Departments of San Francisco, Los Angeles and New York City; the local health officers of places where cases of psittacosis have occurred; the attending physicians of such cases; Dr. Karl F. Meyer and his staff of the George Williams Hooper Foundation, San Francisco, and Drs. T. M. Rivers and G. P. Berry of the Rockefeller Institute for Medical Research, New York, for information on laboratory results.

## Poliomyelitis in San Francisco

IN 1930, the California district experienced its most extensive outbreak of poliomyelitis. Beginning in June, 1930, the epidemic continued through the following March. There were reported 245 local and 50 non-local cases, and 32 deaths. Although no part of the city was free from the disease, it was found that the prevalence was directly proportional to the density of population. Males were affected more frequently than females and 75 per cent of the males were hospitalized.—J. C. Geiger and J. P. Gray, Statistical Study of Poliomyelitis in San Francisco in 1930, *J. Prev. Med.*, 6:145 (May), 1932.

# Contributions of the Western Branch to Public Health\*

KENDALL EMERSON, M.D.

*Acting Executive Secretary, American Public Health Association,  
New York, N. Y.*

THE success or failure of any government in the last analysis must be measured by the well-being of its citizens." The triteness of these words in a recent communication of Governor Roosevelt does not detract from their importance. It is a sentiment that cannot be too often repeated. It is well, therefore, to inquire in whose hands rests the responsibility for the well-being of the citizens of a community.

The obvious answer is that the responsibility rests in the hands of government. But government is an abstraction. It is not an automatic machine which once wound up will run indefinitely on its own momentum. It may be compared rather to an electric current which derives its power from an informed voting constituency and transmits it through elected administrative officers. To this definition should be added the comment that it is human and therefore fallible. Our Constitution states that the objective of government is to secure to the governed enjoyment of life, liberty and the pursuit of happiness. With all three of these objectives public health is inextricably linked. No other single function of government touches so universally every phase of man's existence.

It is this fact which has turned the minds of an increasing number of leaders in medicine into public health channels during the past 50 years. So far-flung a responsibility must be left in no detail to chance. Health administration is no longer a job; it is a vocation. He who is called must dedicate himself to the task with humility, fortitude and self-denial. On his honorable discharge of the duties which his profession imposes depends in very truth the inalienable right of his fellow citizens to life, liberty, and the pursuit of happiness.

The vision of certain early pioneers more than 60 years ago recognized the future magnitude of this responsibility, caused them

\* Presented at the Third Annual Meeting of the Western Branch American Public Health Association, at Denver, Colo., June 10, 1922.

to see the need of adequate professional organization, and led them to the establishment of the American Public Health Association. The career of our Association has not been unfraught with difficulties. So rapidly growing a profession must of necessity be recruited at first from the material at hand, devoted enough, without doubt, but untrained—men and women of the pioneering type who are rather notoriously restless under the restriction which organization implies. In this, the experience of public health is in no wise unique, for every institution in the too rapidly growing fabric of our social development has suffered in kind from the emotional imbalance of adolescence. But through shadow and sunshine the A.P.H.A. has plodded sturdily along justifying in fair weather and in foul the need for its existence, its power for good in promoting the well-being of the people.

The controversial element in human nature is at once its strength and its weakness. Especially do Americans love debate. Vocal minorities are one of our most cherished institutions. The Irishman expressed this well when he said, "Far be it from me to spoil a good fight by rayfusin' to participate." It is somewhat striking as one reviews the history of the A.P.H.A. to note the prevalence of a certain centrifugal tendency. The psychologists call it the schizoid temperament. At the same time they point out that it is not necessarily a characteristic of what we call strength of character, but may rather indicate a certain belligerency and egocentricism, by no means indicative of true greatness. Because of the broad interests covered by our Association and the devotion of its various members to the fields of their special culture, it is in no wise strange that rifts should have occurred. It would have been unhealthy had this not been the case. That we should pass through such periods was inevitable. But it is my firm belief that the day for rugged individualism in public health is over as it is in business and in international relations. We can never possibly all agree, since no one of us is ever wholly right, but we can go far along the road if we will each recognize the limitations imposed by the fact that he is human.

When the Western Branch of the A.P.H.A. was projected, I am informed, there was some hesitancy on the part of the Association in approving the suggestion. This was perhaps based on a natural caution derived from past experience. Almost the first, and one of the pleasantest duties that devolved upon me when I had the honor to assume the acting-secretaryship of the Association was a visit last year to the June meeting of the Western Branch in Seattle. I went as a novice, and as a stranger to much of the historical setting of the national and branch organizations. With no preconceptions, there-

fore, I could fling myself freely into enjoyment of the occasion, and it is a delight to have this opportunity to express the admiration for the Western Branch which that meeting aroused. Never have I attended a meeting where the spirit of coöperation, sincerity and good fellowship more completely prevailed. Nor have I often been at meetings where the papers were so uniformly good, the audience so alert, and the discussion so inspiring. I recall expressing some such feelings at a brief luncheon talk and stressing the fact that, while I hoped the East could still make some contributions of value to the West, I was never so convinced that the East could not possibly do without the priceless contributions to public health work which it lay in the power of the West to make.

We live in a big country and while we may perhaps love it all, yet in the words of Kipling:

God gives all earth all men to love  
Yet since our hearts are small  
Ordains to each one place shall be  
Beloved over all.

We will and should love our own home best, but in its extreme form that virtue becomes a vice as is so well demonstrated in the parochially minded members of our Congress who permit their sectionalism to inhibit the essential functions of our government. Our situation is happier since we are dealing not with a regional but a universal problem. The health of your country can be assured not alone as you do your work well but as the man next door does his equally well. And this principle has nation-wide application. If health were a different thing in California from what it is in Maine, if methods of maintaining the welfare of the people in one region differed radically from those of another portion of our country, we might look with apprehension at the possibilities implied in the development of sectional branches. With common objectives and working on common principles, organization depends on administrative expediency. Strong branches demand strong roots. The national Association will be as strong as the sum of its parts, and the more democratic its organization, the more effective will be its influence.

Now let us examine in brief detail what the Western Branch has done in the 3 years of its glorious existence. Consider first some of the practical results achieved. It has perfected an organization with regularly elected officers, a constitution and by-laws. It provides for an annual meeting where the business of the organization is transacted and scientific papers are presented, while at the same time opportunity is afforded for that most valuable service which a meet-

ing can render, the personal contact and social conference between men of similar interests but so scattered as to render frequent visits impossible.

Membership in the Western Branch includes workers in the 11 western states, Alaska, Hawaii, the Philippines, and British Columbia. These regions possess certain peculiar health problems incident to their vast and often thinly populated extent, their enormous mining and agricultural interests, and their considerable seasonal migrations due to industrial conditions within their boundaries. The West is a territory where travel abounds and visitors from all parts of the world bring with them the special problems of a roving populace. Racial admixtures on a considerable scale prevail in many parts and the adequate care of Orientals, Indians, and Mexicans furnishes constant food for discussion and conference. The opportunity afforded by a closely knit organization for the consideration of such mutual problems is self-evident.

Through the foresight and good judgment of its officers, the Western Branch has established a public health department in the *Western Hospital Review*, a widely read monthly magazine. In this department are published papers selected from those presented at the Annual Meeting of the Branch. The JOURNAL editors have called my attention to the fact that too few articles appear in that publication over the signatures of our western members. While it is fitting that papers dealing with matters of local concern appear in the *Western Hospital Review*, it is equally true that much which emanates from that part of the country has nation-wide interest. So far as is humanly possible in the limitations of the JOURNAL's pages, special articles from the West will always be heartily welcomed and gladly published.

From the start the very efficient Secretary of the Branch introduced a *Western News Letter*, issued monthly by the New York Office, which contains important news items from all parts of the country, but serves the nearer needs of the Western Branch in particular as its official organ. It is read with deep interest by Fellows and members of the Association over widely scattered areas. Lately the A.P.H.A. has adopted the idea for its own use, and two numbers of the Association's news letter have already been issued. In case the Western Branch feels this to be an infringement we will gladly change the form and name, but the idea seemed so good to us that we adopted it *in toto* for occasional national use.

There has been a notable growth in membership for the American Public Health Association as a direct result of the interest aroused in

the western states through the active work of the Branch. This is still evident and, although hard times of necessity slow up the growth temporarily, new members from the West continue with gratifying regularity to send in their applications. The Association leans heavily upon its membership for support and every present member can render inestimable service by stimulating all health workers with whom he comes in contact to join the society both for its larger support and for the unquestioned benefits which membership assures.

I have not exhausted the list of practical benefits accruing from the establishment of the Western Branch, nor have I attempted to forecast its possibilities for the future. These stretch out along a glowing pathway, but I must conclude this discussion after referring to another, less tangible, benefit which the organizers of the movement had in mind and in which their hopes have been abundantly fulfilled.

Last year just before his untimely and greatly lamented death, I had the privilege of talking with Dr. Hassler of San Francisco, who may be called the father of the Western Branch. He described to me the ambition for the more rapid development of public health in his part of the country which had led him to promote and launch the enterprise. He spoke at the same time, and with feeling, of his loyalty to the parent Association. But he referred to the vastness of the country, the limitations of time and money which make it so difficult for a health worker to travel, the need for injecting *esprit* and hope into the mind and heart of the isolated worker whose struggles and successes appeared to bring so little sympathy and reward. It was the man of vision who spoke, a bit bowed down by the titanic task which the public health officer must face, but at the same time buoyed up by the bright picture in human welfare which could be painted when once public health was organized on a genuinely efficient basis. It was this ideal which infused his whole life's work and which was reflected in no small measure in his effort to bring greater solidarity into the public health field by supplying a ready means of closer contact between the workers. This ideal is one to which we may all subscribe and for which we should all fight without capitulation. Mourned and missed by all his colleagues, he was called away while the fruition of his dream was still in the bud. I suggest that we who remain cannot do better than to press on in his footsteps till this organization for the good of the health worker, but far more for the good of the citizens of these several states, shall have achieved the great future toward which his steadfast eyes were turned.

# A County Hospital Health Center

MICHAEL M. DAVIS, PH.D., F.A.P.H.A., AND MARY ROSS  
*Julius Rosenwald Fund, Chicago, Ill.*

THE fundamental job of modern medicine is to keep the patient from getting sick at all; the second, failing prevention, to find him while he still is well enough to be up and about and treat him in home, office, or clinic, to forestall serious illness, if possible. And when both these hurdles have been lacking or have proved ineffectual, there must be the hospital, where both doctor and patient will find all the resources that medical science provides for care and cure.

The Spartanburg General Hospital in Spartanburg, S. C., is unusual, possibly unique, in bringing together under one direction all three of these aims. The hospital itself is a county institution, maintained by public appropriation, private contributions and patients' payments. Its group of buildings consists of the General Hospital with 130 beds for white patients; the Negro Hospital with 50; a building housing out-patient and social service departments, and an isolation unit of 12 beds; nurses' home, laboratory and other service units. Two miles away, the tuberculosis department has beds for 46 white and 20 negro adults, and 30 children.

The unusual quality of the Spartanburg Hospital, however, does not lie in its attractive and adequate plant but in the network of

*The Spartanburg General Hospital, Spartanburg, S. C.  
At the right is the Nurses' Home, at the extreme left the Outpatient Building, which  
houses also the social service department, county health department  
headquarters, and an isolation unit*

service which has spread out from the institution as a center to meet the medical and social needs of the county. Its superintendent, Dr. J. Moss Beeler, is also the director of the county health department, which has its headquarters in the hospital out-patient building. The medical director of the hospital's tuberculosis department, Dr. J. Fabian Busch, serves also as assistant county health director. Laboratory, X-ray, and social services are used alike for in-patients in the three hospital units, for out-patients in the hospital clinics, and the county health department, with its nurses, nutrition workers, itinerant clinics, health centers, and the like. A central record system makes it possible to see at a glance what contacts a patient has had with any branch of the organization. Except in emergencies, free and part-pay patients are admitted to the hospital through social service in the out-patient department. Hospital patients from the county districts are referred on discharge to the county nurses for follow-up.

Through the clinics and nursing supervision in the county, many patients can be saved the necessity of a stay in the hospital; through supervision after hospital care, many can be helped to guard against relapse. Meantime in hospital, clinics, schools, churches, and other community centers, the educational services of the health department are working to prevent the need for care, notably in pellagra and tuberculosis.

In the words of Dr. Beeler:

Our objective is, of course, the health and welfare of our patients and our community. Frequently hospitals consider only care, overlooking the fact that treatment, operations, and so on, only relieve or cure the symptoms of a condition and do not help the community to prevent its recurrence.

Here we have tried to keep in mind first, the comfort and scientific treatment of our patients; second, the belief that any hospital or health center in the South should be an educational center not only for physicians but also for the public. For this reason we use the institution as a meeting place for the County Medical Association, the Nurses' Association, the Community Welfare Association, and the county nurses. The library is open to the personnel. All physicians receive copies of the records of charity cases referred to the hospital.

We realize that if we educate the medical and nursing professions, they in turn will educate the public. Educating the public is the best means of preventing disease. We try to keep before us the ideal that a community needs to be interested in a patient not only when he is with us but before he becomes a hospital problem and after he leaves—so that he will not be obliged to return. It is impossible to separate health from social problems, and hence we work to obtain for our patients whatever they need to help them help themselves, whether it is a well balanced diet, glasses, an artificial limb, or an education.

Spartanburg is on the "fall line" of the Carolinas—the point where the high land drops off to slope toward the sea. In the early

*A ward in the Negro Department*

days the cotton mills came to this district because of the water power; now the streams are harnessed not to mill wheels but to the turbines that make electricity. Throughout the county are the mill villages—each a town in itself with its own churches, schools and stores—to which come families from the back-country districts who have not previously been used to factory life. In the purely agricultural sections about the mill villages, tenant farmers are the rule. Economic depression has fallen on both farmers and mill-workers in the past few years, complicating the heavy burden of typhoid, pellagra, and tuberculosis, which the county shares with the rest of the state.

Against these are ranged the forces of the county health department, headed by the 2 physicians mentioned above, a county dentist, a sanitary director, a director of nurses trained in public health work, and 5 white and 1 colored graduate nurses. The services of a woman physician and the use of a healthmobile have been given to the county by the American Women's Hospitals. A colored physician is employed on a part-time basis for work with the colored residents who comprise about a quarter of the county's population of 123,000. Working with these are 18 industrial nurses employed by the mill owners for the communities; and, through the coöperation of the state and county boards of education, 5 trained nutrition workers (4 white and 1 colored) whose salaries are paid partly out of federal funds, partly by the state and interested individuals and mills.

The work of the county health department includes sanitary supervision of milk and water supplies; and sanitary inspection of schools, camps, barber shops, churches, foodhandling establishments, and private premises; the control of communicable disease through reporting

by physicians; measures for quarantine and isolation; registration and supervision of cases of tuberculosis through regular chest clinics and nursing follow-up, and specific prophylaxis against typhoid, smallpox and diphtheria; supervision and education of some 85 midwives practising in the county; infant, preschool, and school hygiene activities, including the examination each year of all children in one-teacher schools, and of the 1st, 4th, and 7th grades; children in the grade schools with follow-up for the correction of defects and a complete physical examination at the hospital for every high school senior who wishes it, with whatever X-ray and laboratory services are indicated, immunization against typhoid and vaccination. For mothers and "potential mothers"—girls of 16 and over—the department organizes home hygiene classes and Little Mothers' Leagues. It supervises pellagra cases; registers children suffering from orthopedic defects; and carries on an active program of health education, including lectures, motion pictures and health plays, circular letters, pamphlets, health exhibits, and press articles.

In 1930 Spartanburg County appropriated \$17,500 for the county health department and dental program. That year's budget of the department, including income from sales and services, state and federal subsidies for the nutrition program, and money grants from outside organizations, amounted to \$30,792. This figure does not take into account the work of the industrial nurses—an integral part of the county program—whose salaries are carried by the mills, or of the community houses at the mills used by the department as health centers; nor does it include some services utilized by the department but carried in the budget of the Spartanburg General Hospital—laboratory service, for example, or the salary of the county health director, who, as mentioned above, is superintendent of the hospital. The range, variety, and extent of the county work which has been called into being through the modest appropriation of \$17,500 is a tribute both to the economy of the interlocking organization of county hospital and health department and to the administrative skill which enlists and uses effectively the interest of individuals and organizations within and without the county.

In 1930 the department took in \$2,000 from the nominal fees charged whenever possible for antityphoid and toxin-antitoxin administration, and from the sales of dried brewers' yeast as a pellagra preventive to persons who could afford to pay a nominal sum. The salaries of the negro public health nurse and of the part-time negro physician are in part covered by a temporary grant from the Julius Rosenwald Fund. The American Women's Hospitals appropriated

more than \$5,600 to be spent under the department's auspices in educational and preventive work. The Kiwanis Club gave \$500 toward the cost of the crippled children's clinics including provision of braces, special shoes, and plaster casts. The town council and Parent-Teacher Association of Campobello, at the northern end of the county, paid the rent of a Health House or Community Health Center, while the city of Woodruff carried the expense of a health center at the lower end of the county. At each of these a nurse is stationed permanently. In districts other than the two covered by the department's health houses, the community houses of the mills are used for clinics, lectures and the like. The salaries of the 18 industrial nurses working with the department are covered, of course, by the mills, and in many instances mill owners have paid part or all of the expense of a special health project put on by the department in their villages. Aid from the schools and industrial plants amounted to \$3,500 for the year.

Nursing follow-up of cases of tuberculosis within the city is done by the local tuberculosis association, while community organizations such as the Red Cross, Salvation Army, and the like, assist in other special problems. Committees of women are organized in the school districts who arrange for the local school inspections and promote interest in the follow-up of children with defects. After the examination is held, the list of pupils with defects is sent to the school board and by the board to the teachers concerned, the principal of the school, and, if a mill school, also to the superintendent of the mill. Letters are sent to the parents, urging them to have the trouble corrected, and paving the way for the later follow-up by the nurse, if necessary. The director and assistant director devote four evenings a week to health education talks at the community centers, churches, and the like: in 1930 these lectures and motion picture exhibitions reached a total of more than 34,000 persons. One night of the four is given to negro audiences.

Probably no single subject is of greater importance in the preventive campaign broadcast from the hospital throughout the county than that of nutrition, to combat the two serious problems of pellagra and tuberculosis. On the basis of incomplete reporting, it is estimated that there were about 3,000 cases of pellagra in the county in 1930, and the number is believed to have increased here, as elsewhere in the South, during the hard times of recent years. Yet the deaths reported show a decline: 72 in 1927; 51 in 1928; 47 in 1929; 48 in 1930. People now are coming to the nurses and doctors for advice, recognizing the early symptoms and no longer insisting that they are suffering from sunburn or have used too hard soap.

For the past 4 years, the months of February and March have been used for a special campaign against pellagra. Meetings are called of the key groups in the community: the teachers, community workers of the Red Cross and similar organizations; industrial nurses, physicians, home and farm demonstration agents, ministers, club women, representatives of parent-teacher associations, merchants, seedsmen, and so on, at which the program is outlined. To reach those not present at the meetings, a letter is sent to every teacher, preacher and community worker. All of these are urged to arrange talks in the schools and churches and at other meetings on the value of gardens and the need of pellagra preventive foods.

Nurses and club women see to the poster and window displays in post offices, mill offices, and stores. In many instances the industrial nurses have interested the mill owners in having garden space plowed for all who agreed to plant and tend gardens, and have maintained hot-beds for winter gardens. One mill last year had a proud record of 200 gardens. The healthmobile supported by the American Women's Hospitals tours the county visiting all one- and two-teacher schools, while pupils and their mothers go to see the wonders of its tiny kitchen with its gas stove, sink, and electric lights; listen to the talks on pellagra and on general health by physician and nurse; and watch the nutritionist prepare the right food in the right way. In March the 5 nutritionists devote all their time to talks and demonstrations of pellagra preventive foods.

Throughout the year education in nutrition and other aspects of home hygiene is carried on through the clubs for women, girls, and little mothers, of which 20 were organized by the county nurses and 17 by the industrial nurses. The subject, of course, is emphasized constantly in dealing with parents at the well baby, preschool, and school clinics, and in home visits. It is also carried in the simple mimeographed news sheets sent out monthly to teachers and to homes, including those of all farmers in the county with less than 100 acres. Last September's issue of the bulletin and that month's program of nutritionists and nurses were used to stress the planting of winter gardens to give families fresh food through the cold months, but the drought made planting at that time inadvisable, so that a quick turn had to be made and home-canning of present produce emphasized instead. Through special arrangements with the manufacturers, the health department was able to distribute more than 3 tons of brewers' yeast in 1930 at nominal prices, or at need, without charge, through drug stores and at the health centers and the hospital clinics to patients who had a doctor's prescription. "Pellagra is more an educational

problem than a medical problem," Dr. Beeler believes, and as the result of this effort, mobilizing all the forces of the community, the hospital is only rarely called upon to deal with an advanced case.

During 1931-1932 another special project of the department is an intensive 10-month campaign against tuberculosis in one mill village where the disease has shown a high record during the past 5 years, made at the request of the residents, mill owners, doctors, and schools. Family histories have been taken in a house-to-house canvass, including a record of health and heredity, of milk and water supplies, of rooms, beds, and the like. Tuberculin tests have been made of 309 school children and teachers out of a total enrollment of 336, and of 225 workers in the mills and 150 other persons of the community, and all positive reactors then have a complete physical examination, including a chest X-ray at \$3.75 for those who can afford it. Every school child is weighed and measured monthly, and reports are sent to the parents of those who are more than 10 per cent underweight or show other evidence of malnutrition. Classes of the mothers of malnourished children have been organized to make a special study of nutrition, while other classes of women and young girls are studying this and other aspects of home hygiene and child care.

When such special projects as these and the regular activities of the health department have failed to prevent or check illness, or when more intensive examination is required than can be done at the traveling clinics, the patients come in through the social service department to the out-clinics or other services in the hospital. The clinics at the

*The Healthmobile maintained by the American Women's Hospital for the Spartanburg County Health Department*

hospital which in 1930 recorded 1,350 admissions and 2,756 return visits, include as services: medical, surgical, obstetrical, eye, ear, nose and throat, pediatrics, dental, genitourinary, chest, orthopedic, X-ray, syphilological, and psychiatric. The county does not appropriate funds for the out-patient service as such, and except for the social service department, its personnel is part of the hospital force. A nurse from the senior class in the training school serves in the department for 2 months at a time. A clinic fee of \$.25 is charged if the patient can pay it; for syphilis, a treatment fee of \$.50. X-rays are charged at cost if the patient can pay. Nonresidents are not accepted, nor patients who are able to pay for private service or are already under the care of a physician.

In the General Hospital, where white patients are cared for, the full-pay rate for ward beds is \$2.00 a day, while private rooms are from \$3.00 to \$6.00. The social service department, however, has power to fix rates in accordance with a patient's circumstances, or to admit without charge, if the patient is unable to pay. If the family can pay \$.25 a day and no more, that is accepted. Rates in the negro hospital are \$1.00 a day for the wards and to \$3.00 a day for private rooms.

During the present economic stringency patients who could bring farm produce but no money to defray hospital expenses have been permitted to do so, and hams, chickens, fruits and vegetables, and the like, have been credited against hospital bills and added to the current menus, or canned when immediate use could not be arranged. In other instances, arrangements have been made to let unemployed men work out bills incurred by their families by painting, carpentry, and other work under the direction of the hospital's employees.

In 1930 the hospital gave 33,395 days of care at a per diem cost of \$3.86. The daily cost at the tuberculosis unit is \$2.42 and at the negro unit, \$2.05. Thirty-eight per cent of the patients were cared for without charge. The total expense of the hospital for the year was \$141,315. Receipts from in-patients and out-patients and miscellaneous receipts amounted to \$62,749; endowment income, \$7,107; subsidy from the Duke Endowment, \$15,194; county funds, \$54,000. During the past 6 years, reorganization within the hospital, the establishment of the social service department and of a dietetic department under a trained director, and increased volume of care have resulted in marked economies to the county.

In the General Hospital the patient day cost has been reduced from \$6.63 to \$3.86; the average cost per meal from \$.42 in 1925 to \$.27 in 1930. In 1925 the average monthly pay roll, with a daily average

of 34.7 patients, was \$2,600; in 1930, with the personnel serving the group of institutions with a daily average of 92 patients,\* the monthly pay roll was \$3,700. In 1925, the General Hospital gave 11,665 patient-days of care at a cost to the county of more than \$86,000; in 1930, 35,995 patient-days at a county cost of \$45,000.

Land, buildings and equipment of the institution represent a capital valuation of \$728,676. The Duke Endowment Fund gave \$67,500 and the Julius Rosenwald Fund \$40,000 toward the costs of the Tuberculosis Unit, Negro Hospital, and the Out-Patient Building, erected during 1930 (which also houses the social service department, county health headquarters, and isolation unit). The total cost of the three buildings was \$296,000. The furnishing of the new buildings was largely by gifts from the community.

As a county institution, the Spartanburg General Hospital is governed by a board of 9 trustees appointed by the governor upon recommendation of the members of the county legislative committee. In his hospital capacity, the superintendent is directly responsible to this board; as director of the county health department, he is responsible to the county board of health, which includes representation of the county boards of finance and education, and representative citizens.

The hospital is registered by the American College of Surgeons and the American Medical Association and accredited for internships, and its nursing school is accredited by the state board of examiners. The resident staff includes a house physician and 3 internes; the nursing personnel, 8 graduate and 56 student nurses. The laboratory which in 1930 made 10,353 examinations for in-patients, 31,600 for out-patients, is directed by a physician assisted by a laboratory technician and 2 student technicians. The X-ray department is in charge of a member of the medical staff, assisted by a technician and student technician. There is a well organized medical staff of 31 members, an associate staff of 3 consultants in orthopedics, psychiatry, and preventive medicine (in which the superintendent of the hospital serves as a consultant in psychiatry and the director of the tuberculosis unit as consultant in preventive medicine), and a visiting dental staff of 14 members. Relationships with physicians in the county are cordial and active in the work of both hospital and health department.

Through the use of a common personnel, the interest and zeal of its officers, ingenuity in stimulating self-support in patients, and

\* The General Hospital of 130 beds had an average daily occupancy of 92, the Negro Hospital of 20 beds an average occupancy of 21 beds, and the tuberculosis hospital, where 37 beds were available, an occupancy beginning in October, an occupancy of 34. With these three hospitals the total hospital occupancy in the county during 1931 was 38 per cent of the beds available for use, as compared with 25 per cent in 1925. It is impossible to use in full the facilities of the tuberculosis and Negro hospitals.

coöperation with groups both within and without the county, Spartanburg County has achieved a center for medical care and training, for preventive work and community education which would be unusual in far richer sections of the country, and represents a remarkably effective use of the limited resources available locally. By personal knowledge of the communities they serve, the staff and officers of the hospital are able not only to understand the social and economic as well as medical problems that their patients present, but also the measures that will forestall future burdens on both individual families and on the county.

Aside from the training within its walls, the center is doing a valuable educational work in the training of nurses and other members of its personnel to inter-relationships of medical care and social supervision in community and institution. Its usefulness will be further broadened as development of the work for negro patients makes it possible for the Negro Hospital and extramural work to serve more generally for the training of members of that race. The Spartanburg General Hospital and the services coördinated through its direction represent a most unusual and promising example of the three-fold service of modern medicine to the community—prevention, care, and education.

---

## Administrative Practice in Scarlet Fever

AS of 1930, a detailed examination has been made of the isolation and quarantine requirements for scarlet fever in 44 of the larger cities of the United States. In many instances the regulations are decidedly confused and often indefinite. There is also a lack of uniformity in principles involved. There should be prepared minimal restrictions compatible with safeguarding the public health. There is need for clarification of terms and better understanding of the technics involved. Also, uniform terminology would permit progress through comparison of experiences. Evaluation of the bacteriological methods now in vogue, the effect on the communicability of scarlet fever, of degrees in type of disease, age of patient, and geographical and seasonal variations are only a few of the relationships to be determined.—George B. Darling and John E. Gordon, *American Administrative Practice in the Control of Scarlet Fever. J. Prev. Med.*, 6:185 (May), 1932.

# Public Health Aims and Professional Services of Nursing

During Infancy, Preschool, and School Ages \*

HORTENSE HILBERT, R.N.

*Staff Associate on Nursing, American Child Health Association,  
New York, N. Y.*

REASONABLE functions and services of nurses in relation to a public health program during infancy, preschool and school ages are:

## INFANCY

The general public health aim is no longer restricted to prevention of infant deaths and illnesses. To get for the child during this period and later childhood the best possible chance for complete health is the whole purpose. Healthy infancy naturally presupposes good prenatal, intrapartum and postpartum care. During infancy, continuous, systematic medical supervision followed by home supervision and parent instruction are generally considered to be the most important provisions. In securing these the public health nurse contributes the following services:

She helps to get as many as possible of the new-born infants of her community under health supervision. This is comparatively easy through birth reports. Mothers, too, are most approachable at this time.

She urges placing babies under the continuous systematic care of a physician. Whether this medical supervision comes from organized centers or private practitioners depends in each case on what the community has to offer the economic group which the particular family represents. Sometimes organized centers serve the purpose of getting the mother accustomed to well baby service so that she will want it and get it from her physician later as a matter of course. In many cities the eligibility ratings for free or semi-pay care from organized sources are so definitely determined that choice becomes automatic. Usually, however, a considerable degree of guidance in these matters devolves upon the public health nurse.

That she interpret and supplement the physician's instructions verbally or by demonstration in the home, is as a matter of course taken to be the job of the public health nurse if the mother goes to a health center. If advice is given privately by the physician, she may give the same service if desired by the mother and requested and approved by the physician in question.

\* Read before the Child Hygiene Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

She helps to influence the mother's attitude toward breast feeding if the medical opinion of the community indicates this to be desirable.

She helps the parents to establish a suitable routine for the child's day, emphasizing always its importance for the establishment of good health habits later.

She teaches the principles of protection against communicable disease and emphasizes the physician's advice regarding vaccination and diphtheria immunization.

Here as everywhere in public health, what can be done in the way of direct individual instruction counts the most.

The public health nurse has opportunities and obligations for general education of the public as to what constitutes adequate community provisions for infant care; as to what standard of care mothers have a right to expect and will, therefore, demand. Such public opinion is indispensable for attaining the highest standards and completest resources.

#### PRESCHOOL AGE

The public health nurse urges the continuance of systematic health supervision by the physician where it has begun in infancy. Where not, she naturally tries to get it started. Unfortunately, supervision often is not begun until children are ready to go to school, because in many places there are no organized health programs except the school program which is extended to include entrants into school or kindergarten.

The emphasis at this time is mostly on early correction of defects and immunization. The public health nurse tries through visits to the home to convince the parents of the reasonableness of the physician's recommendations. She tries, too, to tie up proper community facilities existing for each child with its family.

Problems during the preschool period, although they include physical care, become more and more psychological. The public health nurse, therefore, is expected to interpret the principles of child psychology and child training and to be effective must know parental education methods.

#### SCHOOL AGE

Public health nursing for children of school age is looked upon as a special branch because it is often administered by a non-health agency, the school. As a matter of fact, the services of so-called school nurses in the past have been confined to comparatively unimportant routine, mechanical duties within the school, which can hardly be called public health nursing. Public health nursing to children of this age is no different in its aims or services than to other age groups.

Children of this age happen to spend a large part of the day in a special environment—the school. The public health nurse adapts the principles and practices of public health nursing to another environment besides the home. She considers another group of persons besides the parents, namely, the teachers who share the responsibility of care and guidance of the children. Her supreme objective is to help educate children directly and through parents and teachers, how best to use the facilities which are part of their community, to make and keep themselves well, not only as school children but later as adults. Her contributions, however, must be consistent not only with the public health provisions of the community but with the general educational objectives of the school as well.

In the school the public health nurse's services can reasonably include the following:

Where health examinations are made by physicians, she assists so as to be intelligent about the physical status of each child, to interpret findings to parents and teachers, and to make plans for the child's improvement. She also supplies to the physician what information she has about the pupil and his environment.

Where there are no medical examinations the nurse may make periodic, individual inspections of pupils. This process of screening may be quite effective when carried on by one who has had much opportunity for observation of physical signs during her hospital experience. It is not necessary to be a high-powered or even an amateur diagnostician to be a very useful detector.

In places where it is not possible for physicians or nurses to hold regular inspections of pupils at reasonable intervals, it is quite clear that the teacher, who is with the children continuously, should be prepared to develop her powers of observation in regard to conditions which need attention. A nurse as a rule does a much better job when she uses her time in helping the teacher, by demonstration and otherwise, than in trying to do the inspections herself, alone. It is still necessary for teachers to learn on the job many of the things which we hope they will ultimately take over as a matter of course. The nurse is apparently at present one person to guide the teacher in health practices.

Advisory conferences with pupils, teachers and parents often have as their outcome good plans for the future health of the child. Conferences with parents in school are not to be regarded as substitutes for home visits, but as supplementary to them, for familiarizing the parents with the health plans of the school. Teacher-nurse conferences for discussion of all health aspects of the school program should be encouraged frequently and regularly.

Everyone realizes, of course, that the inspection, whether by physician, nurse, or teacher, is more than a procedure for finding out what is wrong. It is fully justified only when used as a means of giving personal, individual health instruction, then and there, and later, to the child, to the parent and to the teacher, and to guide in

the use of health resources of the community. The nurse may strengthen and emphasize individual instruction of this kind through group instruction, to bring out points which have been covered in the daily health education processes of the teacher, if any; if not, to stimulate the teacher's interest in such continuous processes.

Special inspections should include:

*Inspections of children returning to school after illness*—This inspection and subsequent readmission may be made by principal or teacher, usually upon written permission from the attending physician or health officer. The nurse has an educational function to perform in impressing parents with the importance of keeping the child at home when ill, and of calling a physician; in pointing out to teachers that children with sore throats, etc., should be at home, in spite of school attendance records.

*Inspections of children referred to the nurse by the teacher*—These are likely to range from pupils retarded scholastically to scratched hands and scuffed knees. Children are referred by the nurse to proper sources for expert diagnosis and treatment. Cases of minor injuries, scratches, etc., should be discouraged from coming to the nurse. If an accident has occurred in school, the teacher or pupils should be equipped to clean the wound and apply a dressing; if at home, the treatment devolves upon a family member. For emergency care of accidents there should be standing orders from the medical director or board, if there is one. Sometimes standing orders for treatment of scabies, impetigo and pediculosis are obtained so that the nurse's instructions to the parents and pupils are definitely based on a doctor's orders.

*Inspection and exclusion of children for communicable disease*—When communicable disease occurs, it is up to the nurse, where possible, to keep the children in school under her observation during the maximum incubation period through frequent inspections for suspicious signs. She is usually expected to exclude pupils when indicated. The principal and teachers may do it instead. There are various types of legal provisions for this type of inspection and exclusion, and the nurse has an opportunity to function in a teaching capacity toward teacher and principal no matter what the provisions.

Some degree of responsibility for the hygiene of the school environment usually falls to the nurse; in rural districts most of it. It is obviously important that teachers and pupils be made aware of the best use of physical facilities for safeguarding and promoting health at all times. As far as health education, in the sense of curricular activity, is concerned, suffice it to say that all public health nursing services can be made of high educational value as all services of the teacher can be made of high health value.

The public health nurse in school nursing service may be expected actually to participate in the formal teaching program by giving those courses or classes which involve nursing knowledge and technic. She should be able to interpret educational implications in health service to school administrators and teaching staff.

In the home her services for the child of school age are like those for other ages. She interprets instruction to parents and to children as to correction and treatment of defects, control of illness, and promotion of health. Only by thoroughly knowing the home can she help to make intelligent and consistent plans for the child's health.

The nurse must coördinate home and school with all health resources of the community if her work is to be of permanent significance. She consults local medical and dental practitioners, who are the unorganized health resources of the community, to explain to them what the school health program objectives are and to show that they in no way conflict with the prerogatives of private medicine and dentistry—quite the contrary. She solicits the advice of these practitioners in regard to individual needs of school children and the whole school health program.

Where there are no organized resources for health and social service, a good public health nurse can do much to help promote and develop them, not for the school only but for the whole community. If these agencies already exist, complete coöperation with them strengthens not only the agencies but the health service to each school child.

Of paramount importance but often neglected is the establishment of advisory committees representing the school, the health and social agencies, to act in an advisory capacity to the whole school health program, including nursing. It seems of particular usefulness, when it is a board of education service. Here the potentialities of public health service, and type of service reasonable to expect, are often less understood than by health agencies. Understanding can be influenced by an enlightened board or committee. There are other tangible services for such committees which are quite familiar.

Where the public health nurse is expected to include secondary schools in her service, she has the same objectives and functions as she had in elementary schools, although her methods and emphasis are somewhat different. She uses the individual counsellor method more than joint conference or home visit, since the student of secondary school age is gradually becoming more responsible for the care of his own body, the correction of his own health defects and for protecting himself and others against disease. If she understands the manifold psychological problems peculiar to adolescence and is sympathetic with the confusions characteristic of this age, she has a unique opportunity for individual guidance.

At the risk of being tiresome I have gone into what must seem unnecessary detail about public health nursing service for the school

child because there is such variety and confusion of opinion as to what school nursing can reasonably be, and as to how nurses should function in relation to the school. The nurse's services during the preschool period, including infancy, are fairly simple and obvious. When it comes to the school child things seem more complicated because of the probability of non-health agency administration, and because instead of serving directly from health agency or agent to home, the nurse must include another group of individuals, the teachers, and another institution, the school, no matter what the administration under which she functions.

If the nurse can, with the professional equipment which she brings to public health, in any way help realize the general aim of having all children everywhere physically and mentally ready to go to school, and of securing health supervision without break from before birth through adolescence, I feel she will have justified her existence. If she will use her professional equipment to teach what can be done and how to those who have the children under their guidance from day to day, instead of doing for the child what the parent can or should do, she will become a much more potent factor in health education.

If all workers in the field of child health, particularly for school children, had clearly defined aims there could be no haggling over prerogatives and no fears of usurping one another's jobs.

---

## Italy's Courses in Child Hygiene

THE National Children's Bureau of Italy has ordered its provincial branches to organize popular courses on maternal and infant hygiene for girls of 16 to 18 years, according to *Maternity ed Infanzia*, of Rome. The courses are to be given preferably in day nurseries and similar child welfare institutions, so that the girls may have practical training as well as theoretical instruction. No diplomas will be awarded in these courses. The granting of diplomas in this subject is restricted to graduates of special courses given for those who intend to take up maternal and infant welfare as a profession.—U. S. Children's Bureau, Washington, D. C.

# Significance of Bone Trabeculae in the Treatment of Lead Poisoning\*

## Lead Studies XVII

JOSEPH C. AUB, M.D., GEORGE P. ROBB, M.D.  
AND ELSIE ROSSMEISL

*Medical Laboratory, Collis P. Huntington Memorial Hospital,  
Harvard Medical School, Boston, Mass.*

IT has been found easier to control the metabolism of lead in the human organism since it was learned that the lead stream runs parallel to the calcium stream.<sup>1</sup> It is now generally agreed that lead is stored in the bones for long periods of time. From this storage place it is gradually liberated, just as calcium is liberated, and therefore may be found in the excreta over a period of months and probably in small quantities for years. This gradual elimination of lead is the result of normal exchange of the inorganic salt content of bone.

In periods of metabolic emergency such as occur during pneumonia, alcoholic debauches, operations, etc., it has been observed that toxic lead episodes develop in individuals exposed to lead but who have previously had no symptoms. In such metabolic emergencies, therefore, the organism may be exposed to an increased stream, which must be derived from the bones. This lead stream can also be liberated, as shown by Aub and Minot,<sup>1</sup> and Hunter and Aub,<sup>2</sup> by using other methods which draw calcium from the bones. Since this treatment was devised, the question has often been asked whether it is preferable to withdraw lead by such therapy or whether it would be wiser to allow it to be excreted in the natural course of metabolic events over a long period of time. The work here reported presents further evidence in favor of removing this stored lead.

Inasmuch as lead metabolism runs parallel to that of calcium, the lead problem becomes essentially a problem of calcium metabolism. In recent work upon the function of bones, Bauer, Aub, and Albright<sup>3</sup> and later, Gyorgy,<sup>4</sup> demonstrated that bone structure could obviously

\* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

FIGURE I—A graphic presentation of the second group of animals. Both calcium and lead determinations were made in these experiments

be divided into two parts: the hard shaft of the bones needed for body support, and the bone trabeculae which, surrounded by marrow, are concentrated near the epiphyses. These trabeculae serve in large part as the readily available storehouse to supply the body with fixed base for metabolic needs, and they largely disappear when the organism is experimentally depleted of calcium by means of a low calcium diet plus acids or parathormone. We are, therefore, faced by this situation: In the emergencies which sometimes precipitate acute toxic lead episodes, inorganic salts may be withdrawn from the trabeculae of bones. It is, therefore, of interest to know how much lead is stored in these trabeculae.

#### METHODS

Cats were used in this study. Some of them were kept on constant, low calcium diets which consisted of meat, occasionally salmon and liver, and water. Others were on a high calcium diet, which consisted of the same diet with milk in place of the water. Cats will remain in excellent condition on either diet for a period certainly well over a year. After the animals had remained on such a diet for 7 to

9 weeks, approximately 200 mg. of neutralized lead carbonate was injected by syringe directly into the trachea and so allowed to gravitate into the lung. In some of the animals this dose was repeated after several months. After varying lengths of time these animals were killed and autopsied. The long bones were sawed in half and freed from bone marrow by digestion with duodenal content or with purified pancreatic ferment. In this way the bones could be thoroughly cleaned without manipulation. The trabeculae, particularly those at the epiphyseal ends, were then cleaned and separated from the cortex. These were analyzed for calcium and lead. The regular lead analysis, as described by Fairhall,<sup>5</sup> with modification for analysis of the bones as described by Minot,<sup>6</sup> was utilized. Fiske's calcium method<sup>7</sup> was used.

### RESULTS

Fifteen animals were so studied, all of which were killed within 4 months after lead was first administered. The results of the analyses are shown in Table I. No conclusions can be reached in regard to the amount of lead stored in different animals, because the amount of lead which reached the lungs, as well as the amount which was absorbed from the lungs, probably varied considerably. The effects of diet, therefore, are not clear in these observations. The interesting finding is that there was a higher concentration of lead in the trabeculae as compared to the bone shaft in all but one animal, an average increased concentration of 78 per cent. This finding becomes more significant when it is observed that the calcium content of the ashed bone is essentially the same in both places—an average of 365 mg. in the cortex and 350 mg. in the trabeculae per gm. of ash. The increased concentration of lead, therefore, is increased not only relative to the total weight of bone but also in proportion to the quantity of calcium present. It

154	High	High	4 mo. 12 days	27.166	18.206	0.299	0.378	4.795	2.240	0.478	0.348	2nd inj. of Pb after 4 mo. Killed 12 days later.
127	High	Low	1½ mo.	27.039	18.130	0.742	0.362	6.026	2.820	1.106	0.319	Died 1½ mo. after Pb inj.
140	High	Low	4 mo. 12 days	22.620	14.605	0.494	0.383	6.065	2.665	0.791	0.345	2nd inj. after 4 mo. Killed 12 days later.
149	High	Low	5 days	11.000	7.134	0.319	0.381	1.476	0.666	0.536	0.360	Died 5 days after inj.

is clear that in these animals lead was present in greater concentration just where it offered the greater danger, for it was stored in relatively large quantities in the areas which liberate inorganic salts when these are needed for the metabolism of the body.

A confirmatory observation was found in children. In a case of fatal lead poisoning, already reported by Dr. Edward C. Vogt,<sup>8</sup> we analyzed the bones for lead and calcium. The cleaned bones were divided into three parts: the dense area at the end of the bone, the spicules from the medulla, and the hard cortical bone. The analyses

of the second series were obtained from the bones of a child who died from appendicitis. X-ray studies had demonstrated a "lead line" in the bones, but the history disclosed no symptoms of lead intoxication. The analyses are shown in Table II. It is clear that the lead

TABLE II.

Area	Weight of Bone Analyzed gms.		Lead per Gm. of Bone mgm.		Calcium per Gm. of Bone gms.	
	Case I	Case II	Case I	Case II	Case I	Case II
Cortex	3.605	7.8409	0.122	0.124	0.202	0.234
Medullary Spicules	2.860	2.3819	0.178	0.313	0.133	0.228
Metaphyses	3.652	2.2662	0.527	0.243	0.124	0.214
Epiphyses		4.5123		0.203		0.204

concentration, particularly in relation to the calcium, is far greater in the areas where bone growth is occurring and also in the trabeculae. The work of Dr. Vogt further shows that, in spite of removal from lead exposure, the dense shadows where the greater amount of lead is present move onward with the epiphyseal line. This indicates dissolving of the lead in its original area of deposit and redepositing of it in areas of bone growth—an obvious source for a continuous lead stream.

#### DISCUSSION

Previous experiments have indicated that the bone shafts, in all probability, metabolize at a fairly constant rate without much influence from acute metabolic variations, while inorganic salts in the trabeculae are easily liberated. The therapy of "deleading" described some years ago by Aub and Minot<sup>1</sup> also strikingly reduces the number of bone trabeculae. The experiments here reported indicate that there is a relatively large deposit of lead in these areas of bone which most readily respond to metabolic change, and it is this lead which therapy probably liberates in increased amounts in the excreta. It is clear, however, from Vogt's X-ray studies that, in children at least, not all this lead is excreted but that as bones grow it is liberated and then redeposited along the areas of growth.

From the point of view of therapy of lead poisoning, it seems clear that it is better to have the patient relatively free from lead in areas which may readily allow it to circulate. This evidence, therefore, seems further to establish the value of deleading. To be able to liberate some readily available lead and then to replace this with uncontaminated calcium salts would seem to be obviously desirable.

### CONCLUSIONS

Lead stored in the bones is present in higher concentration in the trabeculae than it is in the cortex.

In children it is present in the highest concentration in the areas where calcium is being most rapidly deposited.

The practical value of these observations, indicating the value of accelerating lead excretion, is discussed.

# Seasonal Incidence of Whooping Cough in the United States\*

G. E. HARMON, M.D., F.A.P.H.A.

*Department of Hygiene and Bacteriology, School of Medicine,  
Western Reserve University, Cleveland, O.*

THE seasonal incidence of whooping cough has been studied and discussed by many epidemiologists. Hirsch<sup>1</sup> states that for certain European countries and cities the maximum seasonal incidence of whooping cough occurs in the autumn (September, October and November) or in the spring (March, April and May). Crum<sup>2</sup> states that for Aberdeen, Scotland, New York City and Philadelphia the attack rate is highest in the spring and lowest in the autumn. Luttinger,<sup>3</sup> who dealt with data relating to New York City, considered the relation of whooping cough to season paradoxical because its greatest prevalence occurred during the spring and summer rather than during the fall and winter when respiratory infections are most prevalent. He pointed out that the curves of the seasonal incidence more nearly coincide with those of the diarrheal than with those of the respiratory diseases.

In a study of the epidemiology of whooping cough in Cleveland, the author<sup>4</sup> presented data for 1906-1916 which showed that the disease had its greatest incidence in the spring and early summer. Godfrey,<sup>5</sup> who speaks of whooping cough as an epidemiological anomaly, gives the monthly incidence for New York State for 1913-1917, and shows that the peak of maximum incidence falls most frequently in the winter months. He found no evidence of a distinctive summer increase.

Collinson and Councell<sup>6</sup> have recently published data for Maryland for 1921-1929, from which it appears that the percentage monthly incidence of whooping cough for that state is maximal during March, April, May, and July. While the conclusions of the investigators cited may be summarized in the statement that the peak of the incidence of whooping cough tends to fall in the spring or early

\* Read before the Vital Statistics Section of the American Public Health Association at the 1931 Annual Meeting at Montreal, Canada, September 14, 1931.

summer months, still there is evidence that variations from this type of distribution are not infrequent.

Since 1922, the monthly incidence of whooping cough for a number of states has been published in *Public Health Reports*. An analysis of these data was undertaken to determine the type or types of the seasonal distribution which were occurring in the United States. Since the author <sup>7, 8</sup> pointed out that the peak of the seasonal prevalence of diphtheria, measles, scarlet fever, and typhoid fever occurs earlier in the south than in the north, the data were analyzed with the idea of determining also whether a given type of distribution was associated with a definite geographical or climatic area.

TABLE I  
WHOOPING COUGH MORBIDITY AND MORTALITY  
BY STATES, 1922-1929

States	Total Cases	Total Deaths	Fatality Rate	State	Total Cases	Total Deaths	Fatality Rate
1	2	3	4	5	6	7	8

Ohio	85,000	3,310	3.9	Louisiana	4,987	1,425	28.6
California	52,408	2,213	4.2				

The study was restricted to those states which had a total of 4,000 cases or more reported during 1922-1930, and for which morbidity data had been published for each month of the period. Twenty-nine states listed in Table I, meeting these requirements, were included. It should be borne in mind that because of incompleteness of reporting, the data used represent only a sample of the total cases occurring in any individual state, and that the relative size of this sample varies as between the different states. Sydenstricker and Hedrich <sup>9, 10</sup> found that in Hagerstown, Md., 30.5 per cent of the cases of whooping cough seen by physicians were reported, and only 16.8 per cent of all

cases were reported. Green and Moorehouse<sup>11</sup> stated that 78 per cent of the deaths from whooping cough that occurred in Cleveland during 1923–1928 had been reported previously as cases.

While it is recognized that the case-fatality rate depends upon many factors, and therefore may not be an accurate index of completeness of reporting, fatality rates are presented in Table I (columns 4 and 8) to serve as a rough comparative index. The period covered by this table does not include 1930 because information in regard to deaths was not available. It is believed, since there is no evidence that physicians report cases of whooping cough more completely at one season than another, that the data used may be taken as a random sample of all the cases that occurred, as far as seasonal distribution is concerned. The samples available were also considered to be large enough to give a reliable indication of seasonal distribution.

A time series for 1922–1930 composed of the numbers of cases of whooping cough reported in successive months, adjusted throughout to a month of 31 days, was set up for each state. Each series was followed through, and for each complete yearly swing or wave the month of maximum incidence and the month of minimum incidence were noted. In this procedure all yearly waves were included without regard to whether they were epidemic or non-epidemic in character. From Table II (columns 2 and 6) it will be seen that, when all states are considered, March appears most frequently as the month of maximum incidence, and October as the month of minimum incidence. It is during the first 7 months of the year that months of maximum incidence most frequently occur, while it is during the last 4 months that we find most commonly months of minimum incidence. Comparing the northern group of states (Connecticut, Massachusetts, Maine, Michigan, Minnesota, New York, North Dakota, Wisconsin, and Vermont) with the southern group (Alabama, Arkansas, Florida, Louisiana, Mississippi, North Carolina, and Tennessee), Table II indicates that while the month of minimum incidence in both groups occurs at about the same time of year, the month of maximum incidence tends to come earlier in the northern than in the southern group.

This rough method of analysis gives no idea concerning the shape of the curve which depicts the monthly distribution of cases throughout an entire year. In order to obtain information on this point the distribution of cases by months for a year of median—that is typical—incidence is desirable. The method adopted for obtaining such a year is that discussed by the author<sup>8, 12</sup> in outline as follows:

October being most frequently the month of minimum incidence, the so-called epidemiological year was considered to run from October

1 of one year, to September 30 of the next. The time series representing the monthly incidence of whooping cough for each state included 8 such epidemiological years, from October 1, 1922, to September 30, 1930. Each month was then treated independently. For any state, for example, the figures representing the incidence of the 8 Octobers respectively were placed in an array and a central value determined by means of parabolic smoothing. The data for the other months were treated in a similar way. The 12 central values thus obtained (really approximations to the monthly median incidence in each case) were added together and the total considered to represent for the period involved a year of median incidence. The median incidence for each month was next expressed as a percentage of this total. The 12 percentages thus obtained indicate the seasonal

distribution of cases in a year of median incidence and when plotted give a seasonal curve which may be regarded as typical. The results for each state are presented in Tables III, IV, and V.

The various time series were next combined to obtain a composite time series representing the incidence of whooping cough in all 29 states. The percentage monthly distribution of cases for a year of median incidence for this series is given in Table III, column 15. The corresponding curve is shown in Graphs I and II. From the percentages and the graphs it appears, when all the states are considered as a unit, that the maximum incidence occurs in March and the minimum incidence in October. It was thought, however, that the states might be classified according to type of seasonal curve and that some of these types might differ from the general type curve characteristic of all states combined.

When a classification of individual states upon this basis was attempted, it was found that with the exception of the District of Columbia, North Dakota, and Vermont, all fell in one or another of 4 groups. Seasonal curves for Connecticut, New Jersey, New York,

Total cases	1,739	1,049	7,251	526	504	1,724	12,935	10,688	460	1,991	39,862

and Pennsylvania were similar in that they were of low amplitude, were high during January, February, March, and April, and low during August, September, and October. These states comprise Group I. Curves for Maine, Massachusetts, Nebraska, and West Virginia (Group II) were found to have a greater amplitude but otherwise they resemble those of Group I. Data in Table III and Graph I make it possible to compare the curves for each of these groups with that for the 29 states combined. It will be noted that the curve for the 29 states combined is highest during February, March, April, and May, the period of high incidence occurring later in the year than is the case for either Group I or Group II. In interpreting Table III, and also Tables IV and V, it is to be remembered that the figures represent a median or are based upon a median. The characteristics

of this average are such that the median number of cases for a group of combined states is not necessarily equal to the sum of the median number of cases of the individual states included.

Alabama, Arkansas, California, Florida, Louisiana, Minnesota, Mississippi, North Carolina, Oregon, and Washington fall into Group III. The seasonal curve for each of these states is high during April, May, and June, and low during September, October, November, and December. Each curve has a high amplitude. The curves for Illinois, Kansas, Maryland, Michigan, Missouri, Ohio, Tennessee, and Wisconsin (Group IV) differ from those of Group III in that their amplitude is less, and that there is a tendency for the curves to be bi-modal with a high period during February and March and another during June and July. Data for these groups are presented in Tables

IV and V. From a study of Graph II it will be seen that the high part of the composite curves for Groups III and IV comes later in the year than is the case for the curve of all 29 states combined.

GRAPH I. PERCENTAGE DISTRIBUTION OF WHOOPING COUGH BY MONTHS FOR A YEAR OF MEDIAN INCIDENCE FOR GROUPS OF COMBINED STATES.

GRAPH II. PERCENTAGE DISTRIBUTION OF WHOOPING COUGH BY MONTHS FOR A YEAR OF MEDIAN INCIDENCE FOR GROUPS OF COMBINED STATES.

### SUMMARY AND DISCUSSION

The results of the analysis of the data for 29 states included in this study, for 1922-1930, may be summarized as follows:

Seasonal incidence of whooping cough is low during the last 4 months of the year, October being the most frequent month of minimum incidence.

Variations are found as regards the month of maximum incidence when groups of combined states are compared. For Groups I and II, seasonal incidence is highest during the first 4 months, the peaks coming in February and March respectively. The curve for Group II has a lower amplitude. For Group III, seasonal incidence is highest during March, April, May, and June, with the peak coming in May. For Group IV, seasonal incidence tends to be bi-modal, being high during February and March and also June and July.

None of these three types of seasonal distribution of whooping cough seems to be associated with any definite geographical area or unit, composed of states having somewhat similar climatic conditions. However, the southern states and those on the Pacific coast have a seasonal curve with a late peak in May (Group III). Furthermore, the northern states with the exception of Minnesota (March and May), Michigan (June and July), and Wisconsin (August) have an early peak for the most part in January or February. If it be true that the peak

of incidence of whooping cough in the south tends to occur in May and in the north in January or February, then the relation of these high points to one another is the reverse of what has been found to be the case for such respiratory infections as diphtheria, measles, and scarlet fever.

NOTE: The author wishes to acknowledge his indebtedness to Mrs. Donald Eveleth for assistance in making arithmetical calculations and in drawing up the tables and graphs.

## Medical Conditions in Soviet Russia

IN Russia disease is no longer a private and personal matter. Since every inhabitant is a social and economic unit, disease is looked upon as harmful to the State, and restoration of the sick to health, the prevention of disease, and the cultivation of positive health are regarded as State responsibilities. In other words, Soviet Russia is witnessing, for the first time, the efforts of a thorough-going State medicine.

Not that private practice has been entirely abolished in Soviet Russia, for though every physician is required to work 6 hours daily for the State, he may, after that work has been done, treat private patients and be paid for such treatment if any desire him. It has not yet been possible fully to realize the ideal of making competent medical care accessible and free to all in the institutions organized by the State, and it is because of the delay due to insufficient personnel that the doctors still have some private practice. It is believed, however, that private practice is doomed ultimately to be wiped out as the numbers of physicians increase and as State institutions are multiplied.—Lewellys F. Barker, M.D., *The Scientific Monthly*, 35, 1:25 (July), 1932.

## BOVINE TUBERCULOSIS AND HUMAN HEALTH

IN 1901 at the London Congress on Tuberculosis, Robert Koch astounded the world by declaring that bovine tuberculosis, if transmissible to human beings at all, was of no more importance than hereditary tuberculosis, and could therefore be practically disregarded. Without any knowledge of the position which Koch had taken, which was contrary to that of Villemin in 1865 and Koch in 1882, work had been carried on for approximately 3 years at the laboratory of the State Livestock Sanitary Board of Pennsylvania, University of Pennsylvania. The conclusions arrived at were entirely contrary to those announced by Koch, and at that time the work lacked only the inoculation of bovine animals to complete the proof according to Koch's own dictum. This was done in the fall of 1901, and on April 24, 1902,<sup>1</sup> the final paper from this laboratory was read before the Pathological Society of Philadelphia, proving beyond all question that the bovine bacillus was pathogenic for mankind and produced disease in children. The same laboratory published several reports of skin infection in veterinarians and others, in which the germ was isolated and proved to be bovine.

Following the Congress in London, the English appointed a Royal Commission, and the Germans an Imperial Commission. The first

Interim report of the English Commission was made May 16, 1904, and the final report in 1911. The German Commission reported also in 1904, and both of them proved conclusively that Koch's statement was incorrect. In 1908 Koch shifted his ground, admitted that the bovine organism did produce disease in human beings, but did not cause pulmonary consumption. While this had academic interest, from the standpoint of disease and death, it was the difference between tweedledum and tweddledee. Except for our federal Bureau of Animal Industry, city and state health officers, and the work of a moderate number of private bacteriologists, the question has remained in abeyance from that time until 1932.

The National Tuberculosis Association,<sup>2</sup> founded in 1904, for the "study and prevention of tuberculosis," decided formally in 1906 to disregard the dangers of bovine disease and to devote its attention solely to the human bacillus and the human case as a distributor of the germ. So we went along with apparently the great majority of people in their ignorance enjoying a state of blissful security which did not in fact exist. A number of people thought that the question had been definitely settled by the eradication of tuberculosis from dairy cattle, and the pasteurization of milk, both of which measures had proceeded at a fair rate of speed, but cattle tuberculosis is still one of the great economic problems of our country, as well as a menace to human health, especially in the case of those under 15 years of age.

Writers have indulged in rejoicing over the decline in tuberculosis, which is unquestionably very gratifying, and have attributed this to antituberculosis measures, disregarding entirely the correlated work of the public health agencies which abound. It seems that the paper by Biraud<sup>3</sup> was the first to raise the question concerning the relative importance in tuberculosis prevention of general public health work and distinct antituberculosis measures, who made the following statement: "A close relationship between both (general and tuberculosis death rates) would tend to indicate the importance of environmental factors and the general state of health on tuberculosis mortality, as compared with direct results achieved by specific antituberculosis measures."

This led to a study<sup>3</sup> by the statistician of the National Tuberculosis Association in which comparisons in some 14 countries are made between the general death rate and that from tuberculosis. In 5 of these, there seems to be evidence that the antituberculosis work is of some value beyond the ordinary public health measures. In the others the curves run almost parallel and seem to demonstrate—what all except those directly engaged in tuberculosis work have believed—

that antituberculosis work is simply one branch of public health work, and does not supersede it or dominate it.

The year 1932 has brought to us two reports which have aroused intense interest and are destined, we believe, to arouse tuberculosis workers from their lethargy. In 1930, Dr. Fremantle,<sup>4</sup> a Member of Parliament, requested the Minister of Health to "issue, for the guidance of the public, a review of the main facts, experience, and conclusions on which action should be based." This was done, but more important was an Extraordinary meeting of the Medical and Science Councils of the People's League of Health at which a committee of sixty, made up of medical, veterinary and agricultural experts, was appointed. Two subcommittees of 23 each were selected from this general committee and have just made their reports,<sup>4</sup> which show that at least 40 per cent of the cows in Great Britain are infected with tuberculosis; that 0.2 per cent suffer from tuberculosis of the udder; that approximately 40 per cent slaughtered in public abattoirs show naked-eye lesions, and that 2 to 13 per cent (average 6.7 per cent) of market milk from various parts of the country contain living tubercle bacilli. The reports further show that 6 per cent of all deaths from tuberculosis are due to the bovine type of bacilli, that 2,000 deaths and at least 4,000 fresh cases due to the bovine infection, mostly in children, occur annually. It is pointed out that a number of cases of tuberculosis, especially of the lymphatic glands, are not reported, so that 4,000 new cases may be regarded as almost certainly an underestimate of the facts.

Following closely on this in America, comes the report of the Committee on Prevention and Research of the International Society for Crippled Children<sup>5</sup> showing that 10-15 per cent of cases of bone and joint tuberculosis are of bovine origin; that of children who suffer from tuberculosis, from 0-5 years, 21 per cent, and 5-16 years, 26 per cent are infected by the bovine germ. The knowledge of these facts has not yet spread through the country. Most of those who have received this knowledge have been, to put it mildly, astonished. Translating these figures into deaths and cases, it means that 3,500-4,000 children annually die in this country from bovine tuberculosis, and that at least 8,000 cases occur; yet the National Tuberculosis Association, which enjoys a rich income from the Christmas Seal sales, amounting one year to approximately 5½ million dollars, and altogether something more than 65 million dollars, has done nothing except pass soothing resolutions concerning tuberculin testing, pasteurization, accredited herds, etc.

The public owes a debt of gratitude to our Bureau of Animal

Industry and to state and city officials in their efforts to suppress bovine tuberculosis, but practically nothing to the National Tuberculosis Association, which indeed congratulates itself in its latest publication<sup>2</sup> on the wisdom of its decision adopted in 1906. The situation passes the understanding of the ordinary individual. The suppression of bovine tuberculosis by the Bureau of Animal Industry is largely a commercial affair, though many veterinarians are deeply interested in the danger of bovine tuberculosis to human beings—more so apparently than the members of the National Tuberculosis Association.

It is high time for a change of sentiment. The facts were positively proved 30 years<sup>1</sup> ago, and it is hard to see that there is any excuse for the negligence which has been evident. The original name of that body did not specify any type of the disease, but tuberculosis in general.

Who can calculate the number of lives saved and the amount of crippling (tuberculosis ranks second as a crippling disease) avoided if we had followed the advice of Abraham Jacobi, great man and great physician, and had been as active in our efforts against bovine infection of children as we have been against the human?

The facts have been before us for 30 years. They have been proved and re-proved. Is there any excuse for longer complaisance or inaction?

### TEXAS ONLY STATE OUTSIDE DEATH REGISTRATION AREA

FOR the past five years or more the situation relative to the collection of vital statistics in Texas has been under close observation. An enormous amount of work has resulted in the people of the state being fairly aroused to the necessity of proper records of births and deaths. The problems of compensation in connection with the claims of World War veterans have emphasized, as probably nothing else could, the necessity for official records of births and deaths.

Texas has a good registration law, but the state is so large in area and population, that many problems are peculiar to that state

and not found elsewhere. Indexing and filing the enormous number of records is handicapped by insufficient clerical help. A satisfactory organization is restricted by inadequate machinery to function. It is believed that the registration in the state today is fairly complete and probably would meet the 90 per cent requirements of the U. S. Bureau of the Census if the records could be checked. A record that cannot be found is no record.

Texas is a wealthy state and there is no reason why the few thousands of dollars necessary to put the program on an adequate working basis should not be provided. We are confident that funds would be forthcoming if the members of the legislature were made to understand the grave necessity for proper records. The local chambers of commerce, the veterans' organizations, the Parent-Teacher associations, the women's clubs, and the medical societies of the state might well organize to bring sufficient pressure on the legislature to secure this result.

Texas is the only state outside the U. S. Registration Area. Everyone who has to do with public health and the use of these records is looking forward to the day when the term Registration Area may be dropped from our vocabulary and we may refer to the vital records of the United States and not to the records of a restricted area. With the admission of the Lone Star State to the Registration Area, that objective will be accomplished.

Undoubtedly many interesting and intricate problems having to do with the practice of medicine and the practice of public health could be found in this state. Occasionally diseases which are not peculiar to other states are found here, and their extent and menace cannot be adequately understood in the absence of proper records of death.

### PAROLE OF LEPERS

IT is a far cry from the old call, "Unclean, unclean," to the leper of the present day, and it is always a joy to note the progress being made in the control of leprosy as well as its cure.

The most recent report<sup>1</sup> from our National Leper Home at Carville, La., states that 19 patients were paroled during the fiscal year ending June 30, 1931. In the neuropsychiatric service, 17 were examined as candidates for parole, in all of whom the arrest of the disease was quite apparent, and in some there was a complete disappearance of formerly intense neurological disturbances. A special note is struck in this report in telling of the improved morale of lepers and suspects. No longer do the inmates regard themselves as out-

casts from society without hope. While there are always a certain number who abscond, a considerable proportion of these have returned voluntarily for treatment, many even paying their own expenses.

The average daily population of the Home was 322, with a maximum at the end of the year of 337, of whom 63 were new admittances. Of 23 deaths, only 4 were attributed directly to leprosy, nephritis leading with 10, and pneumonia next with 4. Certain departments especially have been enlarged in scope. There is now special treatment of the eye, ear, nose and throat, with the belief that not only can relief for existing disorders be given, but extensions of the disease into these fields may be delayed or prevented. That this enlargement meets a demand is evidenced by the fact that 120,000 treatments were given in this department during the year. A consulting specialist who visits the institution weekly made 10,000 examinations, did refractions, and performed 100 operations. Dermatologic, orthopedic, and dental services are also in operation.

The introduction of additional recreational facilities has produced a marked improvement in the mental attitude of the patients. "The keen competition seems to accelerate both physical and mental functions, broadens views, decreases discontent, and tends to abolish that hand-to-mouth mentality which is so conspicuous in chronic illness."

The decrease in leprosy in practically every part of the world where money and authority are available to carry out what is known scientifically is one of the pleasantest stories that preventive medicine has to tell. The unfortunate leper has suffered from an unreasoning terror on the part of the public. It is a great thing to be able to state that the disease can be arrested and even cured.

## ASSOCIATION OF WOMEN IN PUBLIC HEALTH

THE Association of Women In Public Health will meet at an informal dinner at the Willard Hotel, Monday, October 24, 1932, at 6:30. Women of all sections of the American Public Health Association and their guests are invited to renew mutual acquaintanceships and learn of progress in other sections. Tickets will be \$1.50 per plate and should be purchased at the registration desk.

The International Conference of Women at the Century of Progress Exposition will be discussed.

## NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, providing

such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Washington will be elected for the three-year term, 1932-1935.

Earle G. Brown, M.D.,  
Secretary, State Board of Health,  
Topeka, Kansas.

Herman N. Bundesen, M.D.,  
City Health Officer,  
Chicago, Illinois.

J. W. M. Bunker, Ph.D.,  
Massachusetts Institute of Technology,  
Cambridge, Massachusetts.

M. M. Davis, Ph.D.,  
Director for Medical Service,  
Julius Rosenwald Fund,  
Chicago, Illinois.

W. Thurber Fales, M.D.,  
Director, Bureau of Vital Statistics,  
Montgomery, Alabama.

Wade H. Frost, M.D.,  
Johns Hopkins University,  
Baltimore, Maryland.

- George W. Fuller,  
Fuller and McClintock,  
New York, New York.
- J. C. Geiger, M.D.,  
Health Officer,  
San Francisco, California.
- Willard P. Greene, M.D.,  
Div. of Preventable Diseases,  
Minnesota State Board of Health,  
Minneapolis, Minnesota.
- Alice Hamilton, M.D.,  
Harvard University,  
Cambridge, Massachusetts.
- Norman MacL. Harris, M.B.,  
Chief, Laboratory of Hygiene,  
Ottawa, Canada.
- Ira V. Hiscock, Ph.D.,  
Yale University,  
New Haven, Connecticut.
- Sally Lucas Jean,  
Health Consultant,  
New York, New York.

Chief Sanitary Engineer,  
Department of Health,  
Baltimore, Maryland.
- A. J. CHESLEY, M.D.,  
*Chairman,  
Nominating Committee.*

## APPLICANTS FOR FELLOWSHIP

- HEALTH OFFICERS' SECTION—James N. Baker, M.D., Montgomery, Ala., Joseph Blickensderfer, M.D., New Philadelphia, O., Walter J. Connell, M.D., Dubuque, Ia., William L. Hart, M.D., Omaha, Neb., John L. Lavan, M.D., Toledo, O., Charles B. Maits, M.D., Pittsburgh, Pa., Arthur W. Newitt, M.D., Midland, Mich., Giles S. Porter, M.D., San Francisco, Calif., Lester A. Round, Ph.D., Providence, R. I., James R. Smith, M.D., Erie, Pa., Samuel J. Stewart, M.D., Alhambra, Calif., Jerry E. Vanderpool, M.D., Walla Walla, Wash.
- LABORATORY SECTION—James H. Black, M.D., Dallas, Tex.
- VITAL STATISTICS SECTION—Jerome Meyers, M.D., New York, N. Y.
- PUBLIC HEALTH ENGINEERING SECTION—Lee M. Clarkson, Atlanta, Ga., Henry Duke Peters, B.S. in C.E., Jacksonville, Fla., Louis F. Warrick, B.S. in C.E., Madison, Wis.
- INDUSTRIAL HYGIENE SECTION—Frederick B. Flinn, Ph.D., New York, N. Y., Albert S. Gray, M.D., Hartford, Conn., Adelaide R. Smith, M.D., New York, N. Y.

**FOOD AND NUTRITION SECTION**—Hugh N. Heffernan, B.S., New Orleans, La., Lawrence H. James, Ph.D., Washington, D. C., George C. Supplee, Ph.D., Bainbridge, N. Y.

**CHILD HYGIENE SECTION**—John E. Burke, M.D., Schenectady, N. Y., Helen A. Cary, M.D., Portland, Ore., Isidore H. Goldberger, M.D., New York, N. Y., Louise Strachan, A.B., New York, N. Y.

**PUBLIC HEALTH EDUCATION SECTION**—Maurice A. Bigelow, Ph.D., New York, N. Y., Palmer R. Bowdish, M.D., Provo, Utah, Bertrand Brown, A.M., New York, N. Y., Edward F. Brown, New York, N. Y., Kendall Emerson, M.D., New York, N. Y.,

Florence L. Meredith, M.D., Boston, Mass., George J. Nelbach, LL.B., New York, N. Y., Edith P. Sappington, M.D., San Francisco, Calif.

**PUBLIC HEALTH NURSING SECTION**—K. Frances Cleave, B.S., Harrisburg, Pa., Edith Granger, R.N., Orange, N. J., I. Malinde Havey, R.N., Washington, D. C.

**EPIDEMIOLOGY SECTION**—Milford E. Barnes, M.D., Iowa City, Ia., Howard A. Lanpher, M.D., Des Moines, Ia., Joseph Smith, M.D., Providence, R. I.

**UNAFFILIATED**—Luther M. Boyers, M.D., Berkeley, Calif., Solomon L. Skvirsky, M.D., Holyoke, Mass.

## NEW MEMBERS

*The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated and action by the Section Council will follow.*

### *Health Officers Section*

Levi A. Barnett, M.D., Dept. of Health, Greenwood, Miss., Director, County Health work  
F. G. Bartel, M.D., County Health Dept., Newton, Kans., County Health Officer

Primitivo V. L. Cohen, D.D.S., Calle "27 de Febrero" No. 74 (Altos) Santo Domingo, West Indies, Sanitary Health Officer

H. O. Collings, M.D., Health Dept., Quincy, Ill., Public Health Officer

George Holden Coombs, M.D., State Dept. of Health, Augusta, Me., Director of Health

E. S. Gillespie, M.D., Health Dept., Peoria, Ill., Commissioner of Health

A. Judson Kemper, M.D., Court and Washington, Clarksburg, W. Va., County Health Officer

William P. Prescott, Health Dept., Claremont, N. H., Health Officer

Ralph W. Sanders, M.D., Health Dept., Alameda, Calif., Health Officer

### *Laboratory Section*

Emil Bogen, M.D., Olive View, Calif., Director of Laboratories

Cassius L. Clay, State Board of Health, New Orleans, La., State Analyst, Charge of Bureau of Food, Drugs and Chemical Laboratory

Roscoe R. Spencer, M.D., National Institute of Health, Washington, D. C., Medical Research Worker

### *Public Health Engineering Section*

John B. Harrington, 24 Washington St., S. Charleston, W. Va., Assistant Sanitary Engineer, State Health Dept.

Joseph G. Hildebrand, 35 E. Wecker Drive, Chicago, Ill., Secretary-Manager, Plumbing and Heating Industries Bureau

### *Food and Nutrition Section*

S. H. Loeb, 452 Humboldt St., Denver, Colo., Food, Drug and Sanitary Commissioner

Robert P. Straka, 216 13th S. W., Washington, D. C., Assistant Bacteriologist, Bureau of Chemistry and Soils, U. S. Dept. of Agriculture

T. Lowell Swenson, 216 13th S. W., Washington, D. C., Associate Bacteriologist, Food Research Division, U. S. Dept. of Agriculture

### *Child Hygiene Section*

Barnett H. Cooper, M.D., 122 W. Main St., Glen Lyon, Pa., Medical Inspector of Schools

Eleanore Cushing-Lippitt, M.D., 325 E. Wisconsin Ave., Milwaukee, Wis., Vocational School Physician, Dept. of Health

Eugene C. Peck, M.D., 138 Huntington St., New London, Conn., Epidemiologist, State Dept. of Health

Dr. H. L. Woodside, Bigler, Pa., School Medical Examiner

### *Public Health Education Section*

Harold M. Frost, M.D., 95 Milk St., Boston, Mass., Medical Director, New England Mutual Life Insurance Company

Catharine P. Hanly, 320 Martin Brown Bldg., Louisville, Ky., Director of Health Education, Central Dairy Council

Eric M. Matsner, M.D., 1016 Fifth Ave., New York, N. Y., Assistant Visiting Gynecologist, City Hospital

Charles W. Robinson, M.D., City and County Health Dept., Atchison, Kans., City Health Officer

*Public Health Nursing Section*

Ethel M. Barton, Sullivan County Health Dept., Blountville, Tenn., Staff Nurse

Helen E. Bond, R.N., 210 E. Gaston St., Savannah, Ga., Director, Savannah Health Center

Ruth Burrow, R.N., State Health Dept., Nashville, Tenn., Public Health Nurse

Maude E. Hatheway, R.N., 75 Trinity Ave., Lowville, N. Y., School Nurse

Mrs. R. E. McClung, R.N., 809 Pine St., Trinidad, Colo., Red Cross Board Member  
Margaret A. Paul, R.N., 43 S. Lansdowne Ave., Lansdowne, Pa., Director, Visiting Nurse Assn.

Ora E. Phillips, R.N., Rutherford County Health Dept., Murfreesboro, Tenn., Public Health Nurse

*Unaffiliated*

Miguel Cespedes Alvarez, M.D., Steinhart—Avenue Columbia, Marianao, Cuba, Secretary of Sanitation for Cuba

## LETTER FROM GREAT BRITAIN

### A PLETHORA OF CONVENTIONS?

ALTHOUGH almost annually somebody or other raises a cry that there are far too many congresses, conventions, and conferences, and in the interests of economy something should be done to reduce the number, nothing ever happens. This year, indeed, when it might be believed that the need for economy was particularly obvious, there appear to be just as many, if not more, than usual. Not only so, but the number of delegates appointed, if smaller at all than the average, is very little below.

The congress of the Royal Sanitary Institute which generally attracts from 1,200 to 1,500 persons, will this year register probably at least the lower figure, the number of appointed delegates to date (a month before the meeting) being in the neighborhood of 800. Having regard to the fact that invitations to appoint representatives were only issued about 4 months ago, and much later than usual, this is regarded as a most gratifying response, and as assuring complete success for the meeting.

As usual, the congress will meet in a number of sections and conferences where a variety of subjects of interest and importance will be discussed under the presidency of persons of prominence

and distinction. It is a source of great gratification generally, and particularly to those who are privileged to know him, that Professor Winslow of Yale is to deliver what is known as the "lecture to the congress," and has chosen as his subject, "Current Tendencies in American Public Health."

### CHILD WELFARE, TUBERCULOSIS, AND LOCAL GOVERNMENT

ROUND about the time of the holding of the congress of the Royal Sanitary Institute at Brighton—a seaside and health resort about an hour's journey by rail from London—there will have been or will be held certain other conferences. The most important of these are those on maternity and child welfare, and tuberculosis. Each is to be held in London under the presidency of the Minister of Health (Sir E. Hilton Young), though it is probable that the active part he will take will be limited to the delivery of an address offering encouragement and indicating the need for having regard to the difficulties of the moment.

A congress already held is that bearing the resounding title of International Congress of Local Authorities, 1932. This, though not largely attended, included representatives of most nations.

The subjects chosen for discussion were not too interesting: "The practical working of local authorities," and "Recruitment and training of local government officials." The fact that each speaker appeared to believe, erroneously, that the way in which he could assist in securing uniformity was by describing at length the system in operation in his own country, in the language which only he and his own nationals understood, while others had to wait for a translation before learning what it was all about, did not add to the interest or the gaiety of the proceedings.

#### CITY MANAGERS

INCIDENTALLY, certain delegates from the United States endeavored to frighten the English official representatives to death by pronouncing strongly in favor of the city manager system. With the exception of a few cranks and individuals with views upon, but without experience and knowledge of, local government methods in this country, the generality of persons engaged upon it dislike the manager idea intensely.

To allow of the appointment of such an officer, indeed, would involve a complete alteration of the local government system, if not of the entire mentality of the people. Largely it is because the mentality and the outlook of the peoples differ so very markedly, and were shown at this meeting to be as different as their speech and their mode of thought, that the impression was obtained that as a conference it failed to secure any practical result and must always fail.

Doubtless as an outcome of the gathering there may have come an increase in friendliness and in understanding, and the social functions—some of which, arranged by the Government, the Lord Mayor of London, and others, were of an extreme brilliance—must have created and encouraged such feelings. From the practical local government point of view and that of persons

who have to work the machine, it is open to doubt if it had any value at all, or if any international congress dealing with matters of really domestic concern ever can have value.

#### STERILIZATION OF THE MENTALLY UNFIT

SINCE the National Government came into power a certain amount of pressure has been brought to bear upon the Minister of Health to make some pronouncement on the subject of sterilization of the unfit. Under this pressure, and perhaps on account of the fact that it was brought home to him that in certain parts of the United States something was being done in regard to this problem, the Minister eventually gave a promise that he would set up a committee to inquire into and advise him upon the subject.

This promise has now been kept, and announcement made of the personnel of the committee and the terms of reference. These last are: "To examine and report on the information already available regarding the hereditary transmission and other causes of mental disorders and deficiencies; to consider the value of sterilization as a preventive measure, having regard to its physical, psychological and social effects, and the experience of legislation in other countries permitting it; and to suggest what further inquiries might usefully be undertaken in this connection."

Among members of the committee mention may be made of L. G. Brock (the chairman), who is chairman of the Board of Control, and as such has a wide knowledge of psychiatry; Dr. Wilfred Trotter, an honorary surgeon to the King, who has done a great deal of work on the surgery of the brain; Dr. Tredgold, a specialist of note in psychological medicine, whose textbook, *Mental Deficiency*, is now in its fifth editions; and Drs. E. W. Adams and R. H. Crowley, the former a medical

officer of the Ministry of Health, and the latter of the Board of Education. Dr. Crowley, who spent some time in the United States some years ago visiting various child guidance clinics, is probably known to many concerned in this movement and in the prevention and treatment of mental defect. That the labors of the committee may be prolonged, and that it may be some time before they find themselves in a position to report, is fairly generally recognized as possible.

#### HONORS FOR THE HEALTH SERVICE

AT the new year and on the occasion of his birthday, H. M. The King makes a point of conferring upon such of his subjects as have earned it, or appear or are recommended to him as being deserving of it, certain honors which are in his gift and his alone. This may take the form of a title, or an order, or a medal, and one of the better known British pastimes is to examine with care the "New Year's List," and the "Birthday List," when they appear in the press, to discover if perchance an honor has fallen to a friend or a colleague.

By public health officers particularly, close search is made on every occasion, and only very rarely does it happen that the work done by those engaged in the health service of the people goes unrecognized. The last list, a "Birthday List," which was comparatively short, no doubt because of a feeling that there were other and more serious matters to be attended to, contained an honor for the public health service in the form of a "knighthood" conferred upon Lieut.-Colonel F. E. Fremantle, a member of parliament, a former president of the Society of Medical Officers of Health, and a member of the Council of that Society and of the Royal Sanitary Institute. Sir Francis Fremantle, before his election to parliament, was for a number of years a county medical officer of health. An idealist and an enthusiast in public health and preventive medicine, Fremantle is a tremendously hard worker in parliament and out of it. He is greatly liked and admired by all medical officers of health, who are very proud of the success he has achieved, and especially of this honor which everyone agrees he has thoroughly well earned.

CHARLES PORTER, M.D.

*London*

# PUBLIC HEALTH ADMINISTRATION

## DIPHTHERIA IMMUNIZATION EXHIBIT, HAMILTON, ONTARIO

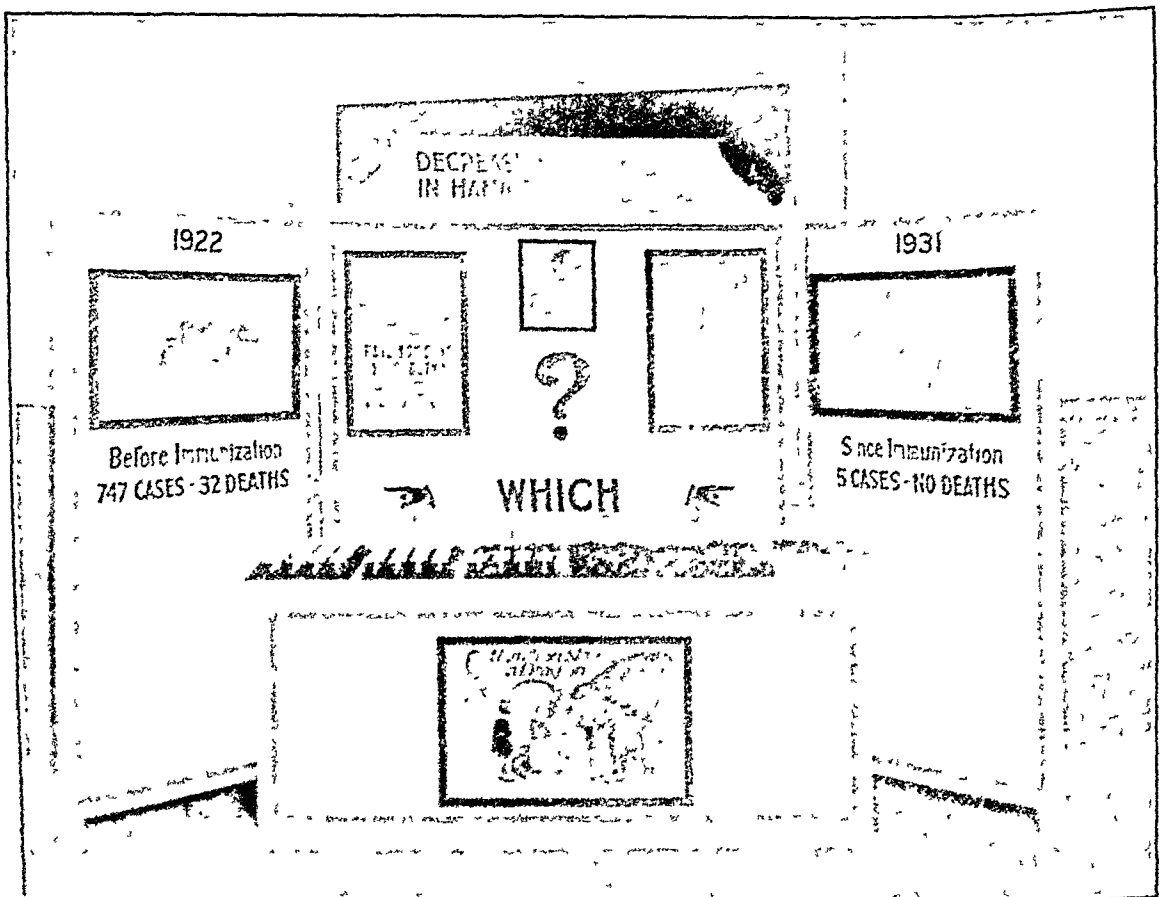

JAMES ROBERTS, M.D., F.A.P.H.A.  
*Medical Officer of Health, Hamilton, Ontario*

IN spite of the success of our diphtheria immunization work since 1922 it was found essential to awaken, or I might say re-awaken interest in the subject, so that the almost absence of diphtheria in the city would not lull parents into such a sense of security that they would neglect to have their children immunized; and to depict to them in a manner that would leave no doubt in their minds that the work had

resulted in a great decrease in cases and deaths.

To do this something had to be evolved that could be easily transported from place to place, that would fit into store windows and similar positions where accommodation was limited, and, above all, that would immediately arrest attention so that the passer-by would stop to look.

The background is made up of three

separate screens manufactured of 1" pine, the panels being of three ply wood. These three sections fit together with brass hinges by means of removable pins. On the left is shown a map of the city in which are placed 747 dark green pins to denote the number of cases, and 32 orange colored pins to show the number of deaths. Over this map "1922" is written. Underneath are the words "Before Immunization"—"747 Cases—32 Deaths." On the center panel are shown three framed posters that have been used in Hamilton at various times to draw attention to diphtheria immunization. Under the small center poster is a large interrogation mark and the word "Which" with a hand pointing to either side. The right hand panel again bears a map of the city showing only 5 green pins, head "1931," and underneath the words—"Since Immunization"—"5 Cases—No Deaths."

In front of this three panel screen is a table with removable legs, surrounded with a panelled screen.

On this table are set up a number of small white crosses, each fitted into a small hole in the table top, which is in turn covered with artificial grass. Each section denoting a particular year is divided by an imitation gravel path. A larger cross with the year written upon it calls attention to the number of deaths in that particular year. Thus, 1920 has 44 crosses; 1922 has 32; 1925 has 14; 1929 has 1, and 1930 has 2.

The end section depicting 1931, in which year we had no deaths, is shown as a vacant field surrounded with a picket fence and adorned with a notice board on which appears "1932"—"Vacant."

On the front of the panel is shown a three colored poster entitled "Hamilton

Slays a Dragon." This depicts a line-up of youngsters receiving toxoid treatments while a nurse, in movie parlance, registers joy. In the background is a fearsome looking dragon sneaking away up over the mountain that borders the southern flank of the city.

The whole exhibit is finished in white enamel with light green trim, with all lettering and picture frames in jet black. This color scheme is very effective, especially under artificial light.

To arrest attention further, wax figures of a nurse in uniform and a small girl were posed in front and on either flank of the exhibit, with a small card held in the girl's hand with the caption "Protect Me Too."

The cost was very moderate, and with the greatest good-will and coöperation on the part of store-keepers and others we have effectively demonstrated to the citizens of Hamilton the fact that toxoid has practically banished diphtheria from their midst.

#### NUMBER OF IMMUNIZATIONS

Year	School Children		Preschool Children		Total
1922-23		1,005		486	1,491
1923-24		3,859		843	4,702
1924-25		2,055		428	2,483
1925-26		2,703		1,302	4,005
1926-27		2,738		1,466	4,204
1927-28		2,931		2,115	5,046
1928-29		1,852		1,788	3,640
1929-30		1,976		2,571	4,547
1930-31		2,011		2,609	4,620
1931-32 (November to March Inclusive)		1,203		1,235	2,443
Totals		<u>22,338</u>		<u>14,843</u>	<u>37,181</u>

NOTE: We are at present engaged in determining the actual percentage of the school population that is immunized, and, while this work is incomplete we anticipate having a figure anywhere between 75 and 85 per cent.

## REVIEWS OF ANNUAL REPORTS

Newport, R. I.—An amendment to the milk regulations provided in 1931 for Grade A pasteurized milk. To qualify for this grade, milk must come from herds tuberculin tested, be effectively refrigerated, have a high butter fat content, be produced under sanitary conditions, and the employees must have medical examinations. There are 6 local pasteurization plants for this city of 25,607. Periodic examinations are made of the ice cream supply in addition to the extensive supervision of milk production and handling.

Cases of communicable disease are cared for at the Newport hospital at a rate of \$3.50 per day. During the year, 704 days of treatment were recorded. Thirty-one new cases of pulmonary tuberculosis were reported with 12 deaths. An infant mortality rate of 42.7 is noted.

Manchester, N. H.—An extensive tuberculosis program is reported for this city of 76,834 population, which includes a clinic and nursing program jointly maintained by the city and the New Hampshire Tuberculosis Association.

The attendance at the clinics has been the largest in any year since the program was inaugurated in 1916. Several reasons may be assigned for this record attendance. First, the active work of the nurses in case finding—particularly in the matter of clinic examinations of all contacts in the families of tuberculosis patients; second, the ever growing interest and participation of the public in the program; third, the difficult economic conditions which are causing increased physical breakdowns of many people.

The admissions to sanatoriums have increased, and a slight increase in active cases is noted, although the mortality rate has continued to decline.

Brookline, Mass.—This community of 48,700 records a general mortality rate of 10.5 and an infant mortality rate

of 29.3. There were 9 cases of diphtheria, with the first death reported from this disease in 8 years. There are records of 8,275 children who have been given diphtheria immunization treatment. About 81 per cent of the births to residents occurred in hospitals outside of the town. There were 12 deaths of residents from tuberculosis, giving a rate of 24.6. This community received the 1931 award in its population class from the U. S. Chamber of Commerce Health Conservation Contest.

Trenton, N. J.—In 1931 an ordinance was adopted forbidding the sale of any milk or cream in the city except pasteurized or certified. A second ordinance provided for the appointment by the Board of Health of a psychiatric nurse. A mental guidance clinic, established in 1930, is in charge of a psychiatrist, assisted by a psychologist, from the New Jersey State Hospital. The new nurse devotes her time to cases in their homes, especially school children, to histories of patients and families, and to assistance in securing medical and other examinations of cases in clinics.

The work done thus far has been of inestimable value to the community. The individual examinations have been painstaking in the extreme and the recommendations as to future care and treatment of patients have been faithfully carried out, with the result that many families have been relieved of what had become almost heartbreaking burdens and we are sure they feel deeply grateful to the municipality for the service.

San Diego, Calif.—A new significance was given Mother's Day in 1931 according to the annual report of the Health Department. In cooperation with the Maternity Center Association of New York, this city took its place in the national campaign to direct public attention to the high mortality rate from causes associated with pregnancy

and child birth. The program included national and local broadcasts, supplemented by news releases on the health of the expectant mother. Letters to all members of the County Medical Society outlined the program and presented local statistical data regarding causes of maternal deaths. Letters urging local clergymen to discourse on "The Newer Meaning of Mother's Day" were received with understanding interest. Many sermons urged upon the public the need to appreciate the importance of proper prenatal supervision. Public health nursing visits were made in an effort to extend prenatal health supervision among the needy.

Floyd County, Ga.—This whole-time health unit considers as its major activity the dissemination of information to the citizens of the county on matters pertaining to modern public health work. The newspaper published at the county seat published 40 articles on the work of the Health Department, and otherwise aided in publicity matters. In the treatment of dietary diseases, such as pellagra, the unit provided 475 pounds of yeast for county patients. Sixty-one persons received antirabic treatment during the year. Child hygiene work included an emphasis on school health supervision. A total of 3,325 complete typhoid prevention treatments were given, besides 645 children immunized against diphtheria, and 1,215 vaccinated against smallpox. This annual report concludes with an interesting financial statement showing that at moderate rates, the prevention work done in terms of immunizations, health examinations, etc., may be considered as assets amounting to \$44,695

for the year, against costs of \$7,644 for the department.

Greenville, S. C.—Among the accomplishments of 1931 were the creation of the office of full-time dairy supervisor for the 70 dairies supplying milk to the city, improvements in the milk supply, strengthened nursing service, medical examination of all food and milk handlers with vaccination against typhoid and smallpox, and increased public health instruction. An infant mortality rate of 48.3 is contrasted with 79.6 for the previous year. There were no cases nor deaths from typhoid, and only 1 death from diphtheria was recorded.—*An. Rep.*, Board of Health, Greenville, S. C., 1931.

Pittsfield, Mass.—In 1931, this city of 50,374 population recorded a resident mortality rate of 9.5 and an infant mortality rate of 50.9. There were only 3 cases of diphtheria, 2 of which were carriers, reported, with no deaths. Two school immunization clinics and a campaign to protect younger children from diphtheria were conducted.

Tuberculosis activities increased during the year by treatment in Westfield of many of the children found by the Chadwick clinic service to have hitherto tuberculosis. By the end of the year, however, these children began to return home, most of them vastly improved in health. From the establishment of anti-tuberculosis work in 1919, until 4 years ago, there was a marked decline in the tuberculosis morbidity and mortality. Since then, the decline has been more gradual. On the *Appraisal Form for City Health Work*, the health officer records a rating of 782.

## VITAL STATISTICS

Vital Statistics for Indiana, 1931—The Vital Statistics Division of the Indiana State Board of Health has made a tentative report for the calendar year 1931. While the number of deaths from certain causes may be changed slightly as delayed reports are received, the rates will not be changed and are substantially correct.

It is interesting to note that the total death rate for the State of Indiana, 11.9 per 1,000 population, is the lowest general death rate ever recorded in the state. The death rates from tuberculosis (61.1), typhoid fever (2.9), infant diarrhea (13.9), puerperal septicemia (2.6), and from all puerperal causes (9.6) are the lowest ever recorded in the state in any year. The death rate from diphtheria (4.1) is the same as that for 1930. There was a noticeable increase in the death rate from cancer, from 104.6 in 1930 to 106.1 in 1931, and from the total external causes from 108.7 to 112.7. Under this classification, homicides showed a slight decrease with the 1931 rate standing at 6.4 per 100,000 population, while suicide and accidental deaths showed increases. The increase in suicide was from 20.0 to 20.6 while that for accidental causes was from 82.0 in 1930 to 85.7 in 1931. One of the most gratifying returns was a substantial reduction in the death rate from organic heart disease from 190.0 in 1930 to 176.8 in 1931.

The 1931 infant mortality rate of 57.4 is the same as it was in 1930, since the slight reduction in the number of infant deaths, from 3,404 in 1930 to 3,214 in 1931 was balanced by a proportionate decrease in births from 59,250 in 1930 to 55,950 in 1931. The puerperal mortality was higher in 1931

than in 1930, 5.6 and 5.5 (per 1,000 live births) for the 2 years respectively. —Indiana State Board of Health, *Month. Bull.*, 35:2-3 (Jan.), 1932.

Smallpox in the United States and Canada, 1931—Reports from 43 states, the District of Columbia, and 8 Canadian provinces indicate a decided decrease in the prevalence of smallpox in these areas during the year 1931. The case fatality rate, however, showed no appreciable reduction.

The total number of cases in the United States and Canada, declined from 44,977, in 1930, to 26,869, in 1931. In the United States alone, the drop was from 43,694 cases to 26,004, and in Canada, from 1,283 to 865. The case fatality rate, however, was not appreciably reduced except in the urban centers of the United States, where the rate recorded for a group of 626 cities was only 0.17 per 100 cases, as compared with 0.21 in 1930. In 85 Canadian cities, there have been no deaths from smallpox during the past 2 years, and only 1 fatal case was reported in 1929.

Of the 26,004 cases of smallpox reported in 43 states last year, at least 86 per cent or 22,413 cases, occurred in but 19 states, lying chiefly in the north central and western sections of the country. Two states—Kansas and South Dakota—reported more than 1 case per 1,000 of population, and 3 others—Indiana, Iowa and Vermont—just barely missed that ratio. Indiana, alone, recorded more than 3,000 cases; Iowa and Kansas, well over 2,000 each, and Illinois, Ohio, Oklahoma and Texas, very close to that number.

The states just mentioned are, by and

large, those in which there is not general acceptance of the value of vaccination and revaccination as preventive measures against smallpox. To appreciate fully the significance of the figures cited above, it is necessary merely to compare them with those of a group of 15 states in which vaccination is the general practice, namely, the states along the Atlantic Seaboard. The population of these 15 states is approximately that of the first group of 19, that is 48,900,000 against 48,711,000. And yet there were only 1,063 smallpox cases reported in these Atlantic Coast States as against 22,413 in the central and western group. The case incidence rate in these Eastern Seaboard States is only 2 per 100,000, as against 46 per 100,000 in the central and western group. Comparing the 3 Pacific Coast States with those on the Atlantic Seaboard, it is found that there were reported more than 3 times as many cases of smallpox (3,421) in the former area as in the latter (1,063), although the population of the Pacific States is only one-sixth that of the Atlantic States. In fact, there were more smallpox cases (1,112) in the single State of Washington, with a population of but 1,589,000, than occurred among the 48,900,000 inhabitants of the whole Atlantic Coast.

These findings reflect the fuller appreciation and more general acceptance of vaccination as a preventive against smallpox among the population of the Eastern Seaboard. If, for example, the same conditions had existed in the Atlantic Coast area as prevailed to cause the high case rate of 133 per 100,000 in Kansas, there would have occurred over 65,000 cases of smallpox in these states instead of the 1,063 cases actually recorded.

It is hard to realize that in this day, with the knowledge of the ease with which smallpox can be controlled, there are communities like Helena, Ark.; Fort Scott, Kas., and Bennington, Vt., where

1 out of every 100 of the population has been infected with smallpox during a single year. What this means can best be understood by supposing the same case rate that was reported for Fort Scott, Kas., to have prevailed in the City of New York. In that case, there would have occurred in 1931 at least 85,000 cases of smallpox in New York. Actually only 1 case was reported in the Metropolis during that year.—Met. Life Ins. Co. *Stat. Bull.*, 13:4-8 (May), 1932.

**Vital Statistics for Italy**—Preliminary returns of vital statistics for Italy in 1930 show an increased birth rate and a decreased death rate over the figures for 1929. The birth rate for 1930 was 26.2 per 1,000 population as compared with 25.1 in 1929, 26.2 in 1928, 27.8 in 1925. The death rate from all causes in 1930 was 13.77 per 1,000 population as against 16.14 in 1929 when the mortality exceeded the rates for 1928 (15.76) and 1927 (15.77). The high mortality in 1929 is striking enough to warrant further examination, for it is entirely out of harmony with the gradually decreasing death rate which the greater interest in and attention to public health are effecting in Italy as well as in a great many other countries.

Analysis of the causes of death in 1929 shows that deaths from diseases of the respiratory system were strikingly higher than during the previous year. Influenza, bronchitis (acute and chronic), pleurisy, pneumonia (all forms), and the other diseases of the respiratory system (exclusive of tuberculosis) took a toll of 154,093 lives in 1929 as compared with 124,914 in 1928. This increase in deaths from diseases of the respiratory system of 29,179 is more than large enough to compensate the difference (21,569) in the total number of deaths in 1929 and 1928. Influenza increased from a rate of 24.8 per 100,-

000 in 1928 to 47.3 in 1929; bronchial pneumonia from 143.7 to 169.5; chronic bronchitis from 26.2 to 33.5; and all other diseases of the respiratory system (exclusive of tuberculosis) from approximately 110.2 to approximately 122.5. It is of particular interest to note that despite the increase in deaths from this group of causes, there was a decrease in pulmonary tuberculosis from 92.3 in 1928 to 89.9 in 1929, and from all other forms of tuberculosis, from 33.1 to 31.5. Usually when diseases of the respiratory system are causing high death rates, tuberculosis rates also are high.

Among the diseases which declined in 1929 over 1928, diarrhea and enteritis (under 2 years of age) showed a drop from 165.0 in 1928 to 148.1 in 1929; and suicide declined from 9.5 to 8.8. The 1927 suicide death rate had been 10.4.—Statistical Tables from *Annuario Statistico Italiano Anno.*, IX:31 and 61, 1931.

**The Achievements of a Century in Belgium**—In commemoration of the one hundredth anniversary of the independence of Belgium, *The Scalpel*, one of the oldest medical journals in existence, has published a special number, in which the most eminent medical authorities of Belgium have summed up the accomplishments of the last century. The authors showed that, while the development of public hygiene in Belgium may appear to have been slow up to the end of the 19th century and to have been confined to the more or less efficient application of administrative or technologic measures, the era of Pasteur opened up paths in which there is evidence of an activity that has brought forth most satisfactory results. The etiology of the various transmissible diseases once established, an adequate crusade was launched against each disease, and excellent results have usually followed.

Such pestilential diseases as cholera, the plague, exanthematic typhus, and smallpox (which in 1870 caused 4,163 deaths in a population of 5,000,000) have completely disappeared from the list of causes of death in Belgium. The country rarely encounters a case of malaria, unless it is one which has been imported from one of the neighboring countries where the disease is still an important health problem. Typhoid fever which formerly made serious inroads on the population and which, as late as 1870 to 1880, caused 4,000 deaths annually, has been reduced to 224 cases in 1927. Diphtheria, which caused more than 4,000 deaths every year up to 1890, and 1,828 in 1900, was responsible for only 254 deaths in 1927. Deaths from scarlet fever dropped from 3,364 in 1870 (5,000,000 population) to 118 in 1927 (8,000,000 population); deaths from measles from 3,320 to 679, and deaths from whooping cough from 3,472 to 863. The mortality from pulmonary tuberculosis, tuberculosis of the bones and of the cerebral meninges, for which a death rate of 350 per 100,000 prevailed in 1870, has been reduced to a rate of less than 90 deaths per 100,000 population in 1927, its death rate having been reduced by three-fourths. Infant mortality, which in 1876 ranged around 167 per 1,000 live births, dropped to 107 in 1922 and to 92 in 1927.

In conclusion it may be stated that, owing to the improvement of the economic, social and particularly the hygienic conditions of Belgium, the number of deaths from all causes in 1927 totalled almost exactly the number reported in 1830 when the population was just about one-half its present number.

The general mortality rate in 1830 was 25.57 per 1,000 population, 23.26 in 1870; 20.85 in 1890; 15.20 in 1910; 13.84 in 1920 and 13.46 in 1927.—*J.A.M.A.*, 98:1490 (Apr. 23), 1932.

**Typhoid Fever in the Large Cities of the United States in 1931**—This report of the typhoid fever mortality in 93 United States cities of more than 100,000 inhabitants, is assembled from reports of deaths from the respective health departments of the cities, and the 1931 rates are based on the population of July 1, 1931, as estimated by the United States Bureau of the Census, except in a few instances in which such estimates were not made; in these cases, the population figures of the year 1930 federal census were employed. No adjustment has been made for resident and nonresident deaths, since such an adjustment would be difficult and would not necessarily result in a statement of true mortality.

Five of the 14 New England cities (Cambridge, Fall River, Lynn, Somerville, Waterbury) had no deaths from typhoid fever during 1931. Boston apparently equals its good record of 1930 with a rate of less than 1 per 100,000. Lowell, which has not had an enviable typhoid picture in recent years, reports a much lower figure for 1931. Springfield, which was the banner city for the period 1926-1930, when the rate was 0.4, did not do as well in 1931, the rate being 2.6 this year, and Hartford shows an average typhoid rate for 1930 and 1931 considerably higher than the average for the preceding 10 years.

The typhoid death rate 1.07 for the New England group as a whole is, with one exception (1928), the lowest ever recorded. These cities have improved their condition relatively with respect to the Middle Atlantic group, the rates this year being almost identical in the two sections.

The cities in the Middle Atlantic states, by far the most populous of the 8 geographic groups, had an average rate in 1931 almost exactly like that in 1930 (1.06 and 1.03 for the 2 years respectively). Reading and Utica had no typhoid deaths in 1931, the latter re-

peating its perfect record for the second successive year. Paterson on the other hand, which had no typhoid deaths in 1930, records a rate of 2.9 in 1931. Newark, Jersey City, Syracuse, Philadelphia, and Camden had the same rates for 1931 as for 1930, and Erie, New York, and Elizabeth had rates substantially the same for the 2 years. Buffalo shows an encouraging decrease from 3.9 to 0.7. Camden and Elizabeth, with rates of 4.2 and 4.3 for the two cities respectively, again bring up the bottom of the list as they did in 1930. The increase in New York (0.9 to 1.1) small, to be sure, but worth noting, seems to be chiefly due to three outbreaks during the second quarter of 1931 caused by unregistered carriers. The skill and thoroughness with which these outbreaks were traced to food handlers are worthy of emulation. More than half of the typhoid cases occurring in New York City, in which the probable mode of infection could be traced, were apparently contracted outside the city.

Five of the 9 cities in the South Atlantic group (Jacksonville 3.0, Tampa 3.8, Washington 3.9, Norfolk 5.4 and Atlanta 12.6) had higher rates in 1931 than in 1930 and 1 (Miami) was stationary. Norfolk again shows an increase and bids fair to have a higher average for the 1930 quinquennium than for the preceding 10 years. Washington also is not quite maintaining its excellent 1926-1930 average of 2.8.

The cities in the East North Central group led all the others in their low typhoid average for 1931. This is in spite of the fact that in Cleveland 20 out of 31 deaths occurred in an outbreak at the State Hospital for the Insane. Without these deaths, the Cleveland rate, would be 1.2 instead of 3.4. The rates in Milwaukee (0.3), Chicago (0.4), and Cincinnati (0.4) continue amazingly low. South Bend, which was first reported among the cities with a population of over 100,000

in 1930, ends its second consecutive year without a typhoid fever death. Detroit seems definitely to have come out of its typhoid period and ranks among the best. This great group of Middle Western cities with nearly 10,000,000 population appears headed toward an almost complete elimination of typhoid.

The cities in the East South Central states have, as is well known, a more difficult problem than those in some other parts of the country. The great reduction in the Nashville rate for 1931 (from 12.3 in 1930 to 3.2 in 1931) is especially noteworthy. This is by far the lowest rate ever reported in that city. Birmingham also breaks its lowest previous record with a rate of 3.0. Memphis, on the other hand, shows an increase from 4.7 in 1930 to 7.3 in 1931, and Knoxville with a rate of 7.3 is also a backslider.

The cities in the West North Central states made their best group record in 1931, Des Moines and Wichita getting a place on the honor roll, with no typhoid deaths, while Minneapolis, Duluth and St. Paul are not far behind. St. Louis continues its excellent record.

The cities in the West South Central states are, as heretofore, relatively high in typhoid as compared with those in other parts of the country, the average for the group in 1931 being about 7 times as high as the averages for the cities in the New England, Middle Atlantic, East North Central and Mountain and Pacific groups. The increased rate in 1931 appears to be due largely

to the increase in the New Orleans rate, from 6.5 in 1930 to 13.9 in 1931. This city, however, is apparently one of those suffering from a high nonresident rate, 48 of the 65 typhoid deaths in 1931 being reported as among nonresidents. Dallas again seems to have more of a typhoid problem than Houston, San Antonio, or Fort Worth. The El Paso rate seems to be coming down satisfactorily.

The cities in the Mountain and Pacific states made a particularly good record for 1931, nearly all of them showing rates as good as or better than those for 1930, thus bringing the group as a whole into close competition with the Eastern states. The typhoid death rate for the Mountain and Pacific cities as a group was 1.07 in 1931. Denver, however, is out of line and had a higher rate (3.4) in 1931 than its 1926-1930 average (2.6).

Twelve of the 93 cities state that no typhoid deaths occurred within their limits in 1931. This is the largest number of cities with perfectly clear records ever reported in these summaries.

The total typhoid rate for the 78 cities whose records are available for the whole 21-year period is almost exactly the same as for the 2 preceding years.

It is too soon to conclude that a stable period in the urban typhoid rate has been reached for the whole country. In the light of past experience, it seems probable that a further decline will be witnessed.—*J.A.M.A.*, 98:1550-1552 (Apr. 30), 1932.

# PUBLIC HEALTH ENGINEERING

## A RURAL SCHOOL SANITATION PROGRAM\*

THE 1930 report of the committee, submitted under the chairmanship of V. M. Ehlers, constitutes a comprehensive study of the activities of various state health departments as regards the field of environmental sanitation. This report was in the nature of a stock taking or survey of the entire field.

The individual sections of the conclusions, together with pertinent portions of the report itself, were brought to the attention of the various committees of the section as a matter of information.

This year, the committee considers it desirable to submit information on a program for rural school sanitation and on suggested standards for it. One of the committee members, W. Scott Johnson, has made this a subject of special study, and has prepared the accompanying brief. It was thought that an outline of a rural school sanitation program already in effect, containing standards and a working plan, would be of maximum interest. One of the most in-

teresting and valuable points brought out in this brief is the importance and value of a rating plan to evaluate the results of the school inspections. This provides the incentive of friendly competition and check-up to insure most thorough work and effort in securing the necessary corrections of any unsatisfactory and unhealthful conditions. Copies of the standard survey report and rating schedule are given with Mr. Johnson's brief. A detailed outline of the standards, giving public health reason for them and information as to satisfactory compliance, is too lengthy to give in this report but is available in mimeographed form.

It is the purpose of the committee, if continued for the coming year, to select another of the subjects recommended in last year's report for the preparation of suggested standards.

## RURAL SCHOOL SANITATION PROGRAM IN MISSOURI

W. SCOTT JOHNSON

*State Board of Health, Jefferson City, Mo.*

OVER a period of years the Division of Public Health Engineering and Sanitation of the State Board of Health of Missouri has developed a program designed to secure better rural school sanitation. Without going into the reasons for this work or the various steps by which the plan reached its present stage, a brief outline of this program as it is working today is sub-

mitted, together with certain results obtained and defects that have become apparent.

The essential features of this rural school sanitation program follow:

1. Annual inspections are required of all rural schools by deputy state health commissioners or their agents in accordance with the regulations of the State Board of Health.

2. Development of regulations and standards of rural school sanitation by the Division of Public Health Engineering and Sanitation; also a survey blank used by the deputy state health commissioners in their annual survey. This is a comprehensive yet concise survey blank requiring only those items to be marked by an (X) which are not satisfactorily complied with and require correction. (See accompanying survey blank.) One copy of this survey report is sent to the school directors, one to the State Board of Health, and one retained by the local health officer. Water containers are furnished by the State Board of Health to the deputy state health commissioners with instructions to collect samples for bacteriological analysis only from properly constructed school wells.

A system of numerically rating school sanitation, using data from the survey sheets submitted by the deputy state health commissioners, was developed by the Engineering Department. This rating can be applied to a single school, all schools in a given county, or to all schools in the state concerning which sanitary surveys have been made out. The ratings furnish an important means of evaluating the results of this work in numerical terms. The attached table indicates the method of rating schools for the entire state.

For example—of the 5,715 schools inspected in the state, 3,899, or 51 per cent. complied with the State Board of Health standards governing drinking water supplies, the possible score for

this item being 40 then the "score earned" under drinking water is 51 per cent of 40, or 20.4.

In the last column, the total of the nine scores is shown as the state score for rural school sanitation. Sanitary scores are also computed for the schools surveyed, on a county basis.

Representatives of the Division of Public Health Engineering and Sanitation have a conference on school sanitation at least once each year with the deputy state health commissioners, in order to encourage the making of school inspections and to instruct them in the technic of school inspections. Usually one or two schools are inspected by the health officer in company with the health department representative.

3. The closest coöperation is maintained with the Education Department and county superintendents, of schools in all matters pertaining to school sanitation. The State Education Department has adopted the State Board of Health standards for rural school sanitation and, further, will not approve any school for a first class rating until sanitation is approved by the State Board of Health. Inspections of all schools for a first class rating are made by personnel from the Engineering Department.

4. The program is essentially educational in character, and persuasive methods for securing improvements prevail, although in a few cases deputy state health commissioners have, with the backing of the State Board of Health, closed schools until sanitary conditions met requirements. As much publicity as possible is given to the importance of satisfactory school sanitation by articles appearing in the press and the *Missouri Public Health News*, as well as public talks before meetings of teachers, school directors, women's organizations, and the general public.

Each year improvements have been made in this program, and the results

indicate material progress. Last year inspections were made of rural schools in 86 of the 114 counties, indicating an increase of 24 per cent over 1929. Of the 8,000 rural schools, 5,715 were inspected, indicating an increase of 23 per cent in 1930 over 1929. The numerical sanitary rating of rural schools in many counties has shown considerable increase, although the state rating has not shown a corresponding improvement. This is explained by the fact that 21 new counties were added last year in which no previous school sanitation work had been done, and the low rating of these balanced the increases in the other counties.

The success of this work is to a certain degree hampered by the following:

1. No law exists requiring the approval of plans for new school buildings.

2. There is need for better training of deputy state health commissioners in the details of school inspections.

3. Inadequate compensation of

deputy state health commissioners by the county courts for school inspection work is a hindrance in several counties.

4. Improved and more complete standards of sanitation for rural schools, including particularly, detailed explanation of the health reason and what constitutes satisfactory compliance.

Certain of these defects will be eliminated in the near future. Under a new state educational law, better supervision of building construction and location will be possible. The deputy state health commissioners are being trained to make more accurate inspections each year by representatives of the State Board of Health. The problem of better compensation for the local health officials is not being solved satisfactorily, except as the number of full-time county health units increase. Improved standards of rural school sanitation are being developed. The first step includes the code on school sanitation giving each regulation followed by the public health

SCHOOL SANITATION INSPECTION REPORT

Form S. E. 2

School ..... No. of Pupils Enrolled .....

District No. .... Name of Clerk ..... Address .....

County ..... Date ..... 193.....

BOARD OF DIRECTORS,  
Gentlemen:

An inspection of your school was made on the above date, and your attention is respectfully called to the following items marked (X) which do not comply with the State Board of Health regulations on school sanitation. I request that the defects indicated below be corrected in compliance with the enclosed regulations.

Sec.\*

- 2 Site: Ample area.....( ).  
Clean, well drained.....( ).
- 3 Building: Solidly constructed; good repair.....( ).
- 4 Drinking Water: Good location.....( ).  
Proper construction.....( ).  
Safe analysis.....( ).  
Individual cups or fountain.....( ).
- 5 Toilets: Good location.....( ).  
Proper construction.....( ).  
Maintenance.....( ).
- 6 Ventilation: 15 sq. ft. floor area per pupil.....( ).  
Shields on windows.....( ).
- 7 Heating: Jacket around stove.....( ).  
Thermometer .....( ).
- 8 Lighting: Light from left or left and rear of pupils.....( ).  
Window space 20% of floor area.....( ).
- 9 Cleaning: Floors clean.....( ).

## INDUSTRIAL HYGIENE

**Results of Profit-Sharing Plan of Sears, Roebuck & Company During the Depression**—This company has a profit-sharing plan started by Julius Rosenwald in 1916. Employees, after one year's service with the company, may become members of the fund and are then required to contribute 5 per cent of their earnings up to \$300 per month. The company's contribution amounts to  $7\frac{1}{2}$  per cent of its earnings before deductions of federal taxes and dividends, and credits to the individual employees' accounts are made on the basis of 1 share to employees with less than 5 years of service,  $1\frac{1}{2}$  shares to those with service from 5 to 10 years, and 2 shares to those with 10 or more years of service. In 1931 the company's contribution amounted to \$1,000,000, and in only two or three particularly bad years has it been less than  $2\frac{1}{2}$  times the deposits of the employees for the year. The funds are invested in the stock of the company purchased at as low a figure as possible.

The plan provides that

. . . after 10 years' service an employee may withdraw and receive his full share of the fund, including the company contributions. An employee with less than 10 years' service receives only his own deposits with 5 per cent interest, unless he is dismissed through no fault of his own, when he receives the full amount. Women who leave the company to get married receive the full amount to their credit if they have had at least 5 years' service, and in case of death the full amount is paid to the heirs or to the estate of the employee.

When the plan was started Mr. Rosenwald stated that its purpose was to permit employees who remained with the company to accumulate a fund which would be adequate to provide for them upon retirement and also to provide an income for employees with long enough service records who do not

remain with the company through their entire business life. The plan also was in part inspired by the desire to secure a stable working force with the lowest possible turnover and to stimulate interest in the success of the company among the employees.

Instances of individual receipts under the plan are cited. Thus a negro porter who was retired a short time ago after 14 years' service drew out \$14,000. His maximum salary had been \$28 a week and his total contributions to the savings fund amounted to \$800. A woman employee who had received a salary well above the average retired recently after a long period of service. She found that her share of the savings fund, invested at 6 per cent, would provide her with an income which was within \$10 a month of her former salary. The average totals accumulated under the plan in 10 years are equal to about 15 times the amount actually contributed by the employee, and this ratio increases rapidly as the period of service lengthens. *Month. Labor Rev.*, 34, 5:1066-1067 (May), 1932.

L. G.

**The Reactions of the Organism to Repeated Electric Shocks (Author's summary)**—Rats were subjected to repeated contacts with electric circuits at 3-day intervals. After contact with a circuit of 248 volts, a certain proportion of the animals showed a paralysis of the hind legs. The incidence of paralysis decreased rapidly with subsequent shocks and disappeared entirely even though the voltage was raised to 1,000 volts. This suggests either that the rats susceptible to the electric current are injured with the first shocks or that they become immune to electricity.

In favor of the latter hypothesis is the fact that the respiratory paralysis and the time required for recovery decreased steadily with increase in the number of shocks. The mechanism of the paralysis is discussed. After a number of shocks

certain rats developed disturbances of equilibrium, priapism, and other signs of hyperirritability of the nervous system.—O. R. Langworthy and W. B. Kouwenhoven, *J. Indust. Hyg.*, XIV, 5:197-205 (May), 1932. L. G.

**Relation Between Industrial Home Work and Business Depression**—In a recent study made by the Division of Women in Industry of the New York State Department of Labor an attempt was made to determine the amount of home work in licensed tenements. The figures are based on the reports of home work inspectors whose duty it is regularly to inspect tenements licensed for home work.

Contrary to what might be expected the results seem to indicate that in periods of depression home work falls off more sharply than factory work.—*Month. Labor Rev.*, 34, 5:1055-1056 (May), 1932. L. G.

**Cadmium Poisoning: II. Experimental Cadmium Poisoning**—This contribution is a continuation of one previously reported in the literature on cadmium poisoning. In the present study cadmium oxide and dust was administered to cats by the respiratory and by the gastrointestinal routes.

By inhalation cadmium oxide fumes or dust produces an increase in the respiratory rate and abundant salivation. Edema of the lungs results from high concentrations with death of the test animals. In smaller amounts pneumonia, bronchopneumonia, emphysema, and atelactasis are produced. Cadmium oxide also produces changes in the liver varying from granulation of the cells to a pronounced fatty infiltration. Fatty infiltration of the kidneys was also found.

With cadmium sulphide dust inhalation, symptoms became manifest after 24 to 36 hours. These consisted in vomiting, diarrhea, increased respiration

and dyspnea. Pneumonia and the lung damage was similar to that produced by cadmium oxide.

The feeding of large doses of cadmium carbonate or phosphate induces vomiting with salivation and loss of appetite. This is absent when small doses are used. Pathology of the liver and kidneys was noted as a result of these feeding experiments. No definite blood changes were observed in these experiments.

In the inhalation experiments cadmium was found to be stored in the lungs, liver, and kidneys, and later in the bones. In the feeding experiments cadmium was retained by the liver and kidneys but the bones also retained some of the material.

Tests with the Burrell mask and Wilson bag respirator for the protection against cadmium oxide and cadmium chloride revealed efficiencies ranging from 73 to 96 per cent.—Leon Prodan, *J. Indust. Hyg.*, XIV, 5:174-196 (May), 1932. L. G.

**On the Effects of Prolonged Exposure to Sulphur Dioxide**—This study is based on the examination of 100 controls and 100 workers exposed to sulphur dioxide gas in industrial occupations. Among the exposed group were 47 employees who had a duration of exposure of from 4 to 12 years. The concentrations of gas in the atmosphere varied approximately from 5 to 70 p.p.m. by volume.

The workers were given physical examinations, and X-ray pictures of their chests were made, as well as blood and urine studies. Biometric studies showed that the two groups were, for all practical purposes, highly comparable. Blood studies showed the control group to have approximately 4 per cent higher polymorphonuclear leukocyte counts and 3 per cent lower lymphocyte counts. Pharyngitis, tonsillitis, and abnormal reflexes were somewhat higher in the

exposed group and the exposed group also presented a considerably larger number of cases of acid urine than did the control group.

The symptoms which showed an increase in the exposed group over the control group were shortness of breath on exertion, increased fatigability during employment, and altered sense of taste or smell. The X-ray findings were essentially the same in both groups. Finally, the incidence of colds was not found to be significantly different in the two groups. The duration of colds was somewhat greater in the exposed group than in the unexposed group.—R. A. Kehoe, F. M. Willard, K. Kitzmiller, and T. J. LeBlanc, *J. Indust. Hyg.*, XIV, 5:159-173 (May), 1932. L. G.

**The Best Temperature for Light Work—The Variance of Working Capacities Under Different Air Conditions**—This paper reports the first of a series of studies of the Holland Air Conditioning Research Program sponsored by the Holland Furnace Company. The program on the physiological effects of air environment was originally planned under three general headings:

First, in investigation of the effects of various conditions on sleep; second, the effect of various air conditions on the capacity for light work; and third, the effect of various air conditions on the capacity for hard work.

In order to carry out this program an insulated room was constructed, about 10 ft. by 10 ft. in floor area, with a ceiling height of 8 ft. The insulation was applied to the inner walls and painted with water-proof paint and varnish. Direct expansion coils were suspended from the ceiling, air circulation was obtained by means of an oscillating fan. The coils have an approximate cooling capacity of 800 B.t.u. per hour. Electric heaters, a steam jet humidifier, and a Silica Gel dehumidifier were also installed. The tests on subjects doing light and hard work are all conducted in this room.

Artists' models were used as the subjects of these experiments and sorting

tests were used as a basis of determining the most suitable atmospheric conditions for light work. The tests consisted in sorting 5 different types of objects from a bowl into suitable boxes, deductions being made for errors in performance. Seven subjects were used in the beginning of this study but later on, owing to the incomplete number of tests, the results of 3 of the subjects' tests were utilized.

From the tests on nude subjects the author concludes:

A summary analysis of these average composite curves shows that the shortest time intervals elapsed within the following temperature ranges:

Dry bulb	83° to 90°
Wet bulb	63° to 78°
Effective temperature	72° to 83°
Relative humidity	45% to 48%

The time interval increases appear to be fairly gradual on the low side of the above mentioned temperature and humidity ranges, while on the upper portion of the scale the temperature curves increase somewhat more sharply and in rather constant increments.

In the tests on clothed subjects the composite curves showed that the shortest average time interval took place under the following average conditions of 75° to 86° dry bulb, 65° to 70° wet bulb, 72° to 77° effective temperature and 58 per cent to 62 per cent relative humidity. On this point the author says:

In looking over the curves of the individual subjects one cannot escape the conviction that the data are insufficient for more definite conclusions. We cannot as yet say that a certain temperature is the best for light work as the average in the points determined makes the curves somewhat indefinite.

When, however, we examine the composite curves the conclusion appears reasonable that the elapsed time for performing the sorting tests drops rather definitely to a certain low point and then ascends. The curves indicate higher temperatures, either the dry bulb or the effective temperature, than are usually considered desirable for work of this kind.

—E. V. Hill, *The Acrologist*, VIII, 5:5-12 (May), 1932. L. G.

## FOOD AND NUTRITION

### Action of an Aerobic Spore-Forming Organism on Evaporated Milk—

An outbreak of coagulation in evaporated milk was studied by the authors. Many cans of the spoiled milk were examined bacteriologically and, while most of them failed to yield an organism, an aerobic, spore-forming bacillus, later identified as *Bacillus cereus*, was isolated from three cans, all of which came from one batch of milk. This organism curdled cans of evaporated milk slowly at 37° C. with no change in the odor and flavor, unless the incubation period was extended, and could be found microscopically for only a short time after inoculation and then only in small numbers. If inoculated evaporated milk was provided with a satisfactory supply of air by transferring it to test tubes, removing a part of the milk from a can or in some other way, the organism curdled the milk rapidly, produced an objectionable odor and flavor and could be found in large numbers microscopically.

Since the organism was found in only three of the many cans of milk examined, it did not appear to be the primary cause of the outbreak. Additional evidence along this line was provided, (a) by the survival of the organism in inoculated milk at 37° C. for extended periods so that it is improbable that the organism had died in the milk failing to yield it, and (b) by an increase in the soluble and amino nitrogen in evaporated milk that coagulated following inoculation with the organism, while the soluble and amino nitrogen in milk from the outbreak were the same as in normal evaporated milk.

Normal cans of evaporated milk showed changes on extended incubation

at 37° C.; these included partial curdling, an increase in color and a change in the odor and flavor. Various lots of evaporated milk behaved differently and pronounced differences between brands were encountered. The results suggest that there are variations in the condition of the milk from the standpoint of its resistance to changes by heat. The outbreak of coagulation supplying the milk studied occurred at a time when the atmospheric temperatures were very high, so that a tendency to an instability to heat would have been much more likely to result in coagulation than at other seasons.

The striking thing in connection with the action of *B. cereus* in cans of evaporated milk was the coagulation with no change in the odor or flavor, unless the incubation period was extended.—B. W. Hammer and R. V. Hussong, *J. Dairy Sci.*, 15:220 (May), 1932.

**Vitamin Content of Three Varieties of Spinach**—Studies were made with three varieties of spinach—Virginia Savoy, Princess Juliana, and Viroflay—to determine whether any correlation existed between vitamin potency and leaf type or leaf color. The vitamins A and B content of the three varieties of spinach tested were about equal. Results indicated that Princess Juliana probably contained slightly less of vitamin C than the Virginia Savoy and Viroflay. No relationship between leaf type and vitamin A or B content was detected. The variety with heavily savoyed, bluish-green leaves seemed slightly less potent in vitamin C than the other two varieties.—Hilda Black Kifer and Hazel E. Munsell, *J. Agri. Res.*, 44:767 (May 15), 1932.

**Ferrous Iodide as a Substitute for Vitamin A in Rats**—This is a report of a reinvestigation of a claim made (*Science* 68, 1766, 432, 1928) that small doses of syrup of ferrous iodide can substitute for vitamin A in the cure of xerophthalmia and promotion of growth in rats on vitamin-A deficient diets.

Albino rats from a stock raised for generations on Sherman Diet 13 were placed at 4 weeks of age on Sherman vitamin-A free diet 380 plus irradiated ergosterol (1 mg. per 1,000 gm. of diet). Two series were studied—one in which the syrup of ferrous iodide was given as curative measure after xerophthalmia had developed, and the other in which the iodide solution was given as a preventive measure.

In Series I, 45 rats were given iodide treatment daily, when xerophthalmia appeared—usually at about 9 weeks, when constant weight was reached. Iodide treatment had no effect whatever on the incidence of terminal infections of the glands about the mouth so characteristic of vitamin A deficient rats. In 100 per cent of the animals, both with and without iodide treatment, pus was found at death in one or more of the following loci: submaxillary gland, sublingual gland, thyroid, nasal sinuses, and frequently in the middle ear. Death was hastened by ferrous iodide, by an average of 12 days; although the weight at death was about the same for iodide treated as for untreated rats, the difference being 5 gm. or less. Food consumption was less in the iodide treated rats, the average difference being 25 gm.

In Series II, 18 rats were given daily doses of 3 or 5 drops of dilute syrup of ferrous iodide from the beginning of the experimental period until their death. When so given, the iodide had no effect upon the incidence of terminal infections of the glands about the mouth, nor upon the incidence or course of

xerophthalmia, although it did delay the onset of xerophthalmia, and the time of appearance of constant weight and death. It also increased food consumption.

These results confirm previous work in which it was shown that syrup of ferrous iodide was without effect on the xerophthalmia of vitamin A deficient rats, and further show that ferrous iodide cannot substitute for vitamin A in the cure or prevention of terminal infections characteristic of vitamin A deficiency in rats.—Hazel C. Cameron, *Science*, 76:19, 1957 (July 1), 1932.

**Vitamin B Complex**—Ross and Robertson placed a group of young rats on a vitamin B free diet, and a second group on a similar diet plus 6 per cent dried brewer's yeast. Both groups were infected by mouth with an enteritidis organism. Of 53 rats on the diet deficient in vitamin B, 10, or 19 per cent, survived the infection, whereas of 51 rates given the yeast in addition, 38, or 75 per cent, survived the infection. The authors conclude that the addition of the vitamin B complex to the diet lacking in this factor increased the resistance of the rats against infection.—J. R. Ross and Elizabeth Chant Robertson, *Am. J. Dis. Child.*, 43:547 (Mar.), 1932. Abstract, *J. A. M. A.*, 98:2317 (June 25), 1932.

**Growth under Vita Glass**—The fact that many experiments with vita glass have been uncontrolled and that there has been difficulty in determining what is a "normal" human being, was responsible for this undertaking with rats in a controlled experiment. Pedigreed albino rats were used—two groups of males and females under ordinary and under vita glass, and two mixed groups under each glass. Healthy animals, 30 to 32 days old, were used and maintained during the experimental period on an adequate diet (Sherman B.

*ad libitum*). Weighings were made every alternate day, and the experimental period was from the first of March to the end of October. During this period the growth curves of the groups are essentially identical; that is, no difference between those under ordinary glass and those under vita glass.

In discussing the results, the authors raise the question as to whether any growth above normal which may be exhibited by experimental animals under vita glass is of any biological value; in other words, that the normal growth may be optimal growth. Other factors are discussed such as the intensity of ultra-violet radiation and the transmission factor of the glass. In this experiment too the animals are exposed to direct sunlight which is not usually possible with humans in ordinary house construction.

Reference is also made to the meager supply of ultra-violet radiation in winter, the loss in transmission through the glass which must be scrupulously clean, the importance of exposure to direct sunlight, the necessity for removing clothing, and the high cost.

As an additional experiment, 20 rats were divided—10 under vita glass, and 10 under window glass, and exposed to a mercury vapor lamp on alternate days, 4 feet from the burner. Growth curves were the same as in the previous experiment.—Ian N. Sutherland, *J. Hyg.*, 32:211 (Apr.), 1932.

**A Study of the Calcium Retention on a Diet Containing American Cheddar Cheese**—Two healthy young women, weighing 51.3 and 50.2 kg. were the subject of an experiment to determine the utilization of the calcium of cheese, since milk is rich in calcium and no experiments were previously reported on the availability of calcium in Cheddar cheese. The calcium content of the American Cheddar used in this work was 0.74 per cent. The studies

included 18 consecutive days of two 9-day periods each—one on cheese diet and the other on pasteurized milk. During this time the subjects were not exposed to direct sunlight.

The cheese was made from milk subjected to flash pasteurization at 160° F. and the milk used was fresh, pasteurized at 142° to 145° F. In the two subjects the cheese supplied 86 and 85.7 per cent of the total calcium and the milk 87.7 and 87.4 per cent. The average daily calcium intake on cheese diet was 10.2 mg. per kg. and on the milk diet, 9.4 mg. per kg. body weight sufficient for calcium equilibrium as indicated by previous investigators. The daily average balances of the cheese diets were +0.005 gm. and -0.040 gm., and on the milk diets these balances were -0.010 and -0.031 gm.

One subject showed a negligible positive balance on cheese and a negligible negative balance on milk, or almost remained in calcium equilibrium. The other subject showed slight negative balance both on the cheese and the milk diets, indicating no essential difference between the utilization of the calcium in cheese and that of pasteurized milk.—Marguerite G. Mallon, L. Margaret Johnson and Clara R. Darby, *J. Nutrition*, 5:121 (Mar.), 1932.

**Failures to Produce Experimental Dental Caries in the White Rat with High Carbohydrate Diet and Bacillus Acidophilus or with Vitamin D Deficiency**—Reference is made to the modern scientific studies of dental caries including the parasite theory, the fermentation of carbohydrate materials, influence of Lactobacillus acidophilus and the effect of vitamin C and vitamin D deficiency.

To offset the possible effect of the faulty nutritional condition of the mother during gestation, the experimental animals were the fifth generation of an inbred stock on a liberal diet which

was evidenced by the large size of the animals at weaning time. Thirty-day old animals were given an adequate diet supplemented with Viosterol, fresh green cabbage, and brewer's yeast. The ears of both groups were infected with pure cultures of *B. acidophilus*.

At the end of 9 months the rats were killed and examined for dental caries but none was found. Similar results occurred when cabbage was replaced by lettuce and the starch replaced by sucrose, and in addition to inoculation the teeth and gums were rubbed daily with cultures of *B. acidophilus*.

In a second series on a rachitogenic diet, 4 out of 10 rats received an addition of Viosterol. Three of the 4 rats which survived the 13-months period gave no evidence of rickets or bone or joint deformities. Those on the rachitogenic diet without Viosterol showed marked rickets, bone and joint deformities, but the teeth in all of the series exhibited no caries. In all cases the teeth were removed, carefully cleaned, polished and sectioned, and no microscopical evidence of caries was found.—C. A. Lilly, *J. Nutrition*, 5:175 (Mar.), 1932.

**Recent Studies of the Vitamin A and C Content of Dried Apricots and Figs**—The vitamin C content of fresh

Calimyrna and Kadota figs is about one-half that of fresh peaches or prunes, 20 to 30 gm. daily protecting a standard guinea pig against scurvy. Mission figs show less antiscorbutic effect.

The dried figs (Calimyrna and Mission) retained little of this vitamin whether the figs were sulphured or unsulphured, indicating in this fruit that sulphuring does not protect vitamin C in drying. Calimyrna, Kadota and Mission figs contain more vitamin A than grapes but less than apricots, peaches and prunes. In the dried Missions and Calimyrnas sulphuring protected somewhat the vitamin A, dried Missions losing four-fifths unsulphured as against one-half when sulphured.

Cooking of fresh apricots reduced the vitamin content more than in the case of sulphured dried apricots. There is slightly greater loss of vitamin A in cooking unsulphured fruit than with the sulphured. After 6 months storage, dried sulphured apricots, whether raw or cooked, retained about one-half the vitamin C of the fresh fruit. The stored fruit contained 18 to 29 per cent of vitamin A which was not affected by cooking. Apricots are a rich source of vitamin A even after a loss of 70 to 85 per cent of this accessory.—Agnes Fay Morgan, Anna Field and P. F. Nichols, *Fruit Prod. J.*, June, 1932, p. 304.

---

**Investigations Concerning the Effect of Ultra-Violet Light on the Bacterial Content of Milk and of Water**—Experiments were made on the bactericidal action of ultra-violet light on milk and on water using Wamoscher, Hanua, Scheidt, and Vita-Ray-Gesellschaft forms of apparatus. Disinfection of milk by ultra-violet light was unsatisfactory. The rays never destroyed

as many bacteria as pasteurization. In clear water the rays destroyed 99 per cent of the bacteria so that with the high bacterial content generally found in practice, disinfection was not satisfactory.—L. Vogeler, *Milchwirtschaftliche Lit.-Bern.*, 1930, 41:484; *Wass. u. Abwass.*, 28:100, 1931. From *Summary of Current Literature, Water Pollution Research*, V, 4 (Apr.), 1932.

# CHILD HYGIENE

## CHILDHOOD AND THE DEPRESSION

IT is high time to take stock of what is happening to the childhood of our country in this prolonged period of depression. So many loose and ill-advised statements have been made recently regarding the "high health" of American children, that we should turn to those who are in intimate daily contact with medical and social problems, in order to correct false impressions.

While it is true that the infant mortality rate has continued to decline and that the babies of this country have been, on the whole, well provided for, it by no means indicates that our pre-school and school children are in a satisfactory condition. On the contrary, reports coming in from various sections of the country state that malnutrition and undernutrition appear to be on the increase, and that it is only through heroic efforts to feed our school population that the children are barely kept from stepping over the starvation line. But physical deterioration is not the only effect of such a period. Social maladjustments and delinquency are multiplying. The widespread uncertainty and instability of family life seriously affect the children.

The results of depression upon childhood have been set forth clearly in a pamphlet published by the National Education Association.\* After discussing the financing of education during this depression, the report takes up the increased responsibilities of auxiliary school services.

Along with the increase in attendance, many public school systems are being called upon to operate or to supervise the operation of

special non-educational and relief services. Like the increase in attendance, this tendency is merely a temporarily accelerated part of a movement to assign ever increasing child welfare responsibilities to the schools. Whether such responsibilities are a legitimate school function is not the question at issue. The facts are that such relief functions have frequently been allotted to the schools, and that current economic conditions make this work more difficult and expensive. Perhaps the most important relief function assigned to the schools is the supplying of clothing and one or more meals daily to destitute children.

In a few cities the actual operating expense of these services is assumed by the school system, but in most cases the food and clothing are supplied through the American National Red Cross, the American Friends Society, or through other national or local relief agencies. The cost of administering the relief, however, is often handled in part or whole through the school budget. Other auxiliary school services which are probably carrying an unusually increased load due to the depression include: medical and dental clinics, school nurses' services, vocational guidance, libraries, social case work, and free textbooks and supplies for indigent children.

An important phase of the relief work for which schools are being held responsible is the financial contribution of the teaching profession to local relief funds. On September 18, 1931, the President of the National Education Association issued a message on relief, commending the activities of teachers in relief work and urging "that every member of the profession extend immediate aid to make effective the plans and policies of regularly constituted relief agencies." While even an estimate of the amount contributed by teachers to relief work is impossible, the total is certainly a large one. A few examples will serve to show the general nature of the work done.

In New York City, for example, the school relief fund contributed by the school employees was \$452,000 in 1930-1931 and \$1,000,000 in 1931-1932. Teachers forwarded to the relief committee 2 or 3 per cent of their salaries. The extent of the school relief program may be glimpsed from the following facts for 1930-1931. Many of these figures will be more than doubled in 1931-1932.

\* *Childhood and the Depression*, National Education Association, Washington, D. C.

Free lunches served in a single week	9,800
Pairs of shoes distributed	61,500
Garments distributed	120,000
Cost of milk and crackers, alone	\$26,000

The responsibilities of the teachers are suggested by the following statement:

Teachers and other employees are to detect and investigate need and extend immediate help. Thus the teachers are at once contributors to the huge charity fund, the social workers that discover and inquire into the poor pupils' wants, the direct disbursers of free lunches, shoes, and clothing, and also the bookkeepers and administrators of the funds.

In Newark, N. J., the City Teachers Association organized, at the suggestion of the superintendent, with the approval of the Board of Education, a central relief committee. A fund of \$18,851 was raised from school employees by the first appeal. Cooperation with the Social Service Bureau and with other welfare agencies was immediately established. The program of relief was maintained on a 12-month basis through 1931. A few facts concerning the work of the Newark school relief fund follow:

Pairs of shoes bought	3,170
Number of children served milk	2,853
Total number of meals served	53,328
Total number of pupils assisted	8,047

The fund was used entirely for relief, the small administrative overhead being paid for by the public school system.

From Kansas City, Mo., comes the report that teachers increased their giving to the Community Chest 75 per cent over last year. Teachers are cooperating in the relief work of the Junior Red Cross, and school nurses are paying for needed medicine when the family cannot do so. In Detroit, \$26,488.81 was contributed last year to the Mayor's Unemployment Relief Fund by the teaching force and the present rate of contribution is \$4,000 a month. In Chicago, 11,000 hungry school children were given food by teachers who were themselves financially embarrassed by the failure of the Board of Education to pay them.

The general scope of the program carried on in Philadelphia is suggested by the following report.

Early in 1920 officials of the public school's medical inspection division discovered that many children were seriously under-nourished. Investigation showed that hundreds were coming to school without having had breakfast. A committee of

school executives was appointed to consider the situation. While it was felt that serving breakfasts in school was not of itself a function of the school system, the teachers could not instruct children who were suffering from the pangs of hunger. The principals of all schools pledged unanimous cooperation to meet the emergency. Contributions came in without solicitation. Teachers, clubs, school entertainments, interscholastic football games, and individual philanthropists contributed money and food.

Breakfasts were served to the children in 128 school buildings and in 3 special centers. The breakfasts were available daily, including Saturdays, Sundays, and holidays. The serving was supervised by principals and teachers in the schools, and in many cases the actual preparation and serving of the food was done by the same persons. The largest number of children served in a single day was approximately 8,600. The average gross cost of each breakfast was approximately 8 cents.

In order to avoid undue imposition by those not needing or deserving this care, a monthly check-up was made of each individual case. The details of the diet were worked out by the Medical Inspection Division, the Director of Home Economics, and the Director of School Lunches. The breakfasts were planned early enough in the morning so that the children thus fed might rejoin their companions before the actual opening of school, thus reducing the publicity that might attach to these children.

The work of a single school in Fresno, Calif., is thus described by its principal:

As many children as possible are furnished lunches by the Parent Teacher Association, but many lunches are paid for by the cafeteria manager, teacher, and principal. During 1930-1931, clothing and shoes for over 25 children . . . A large part was paid for personally by interested teachers . . . Teachers this year have over-subscribed their quota to the Community Chest by 25 per cent. Teachers come in intimate daily contact with children who are hungry and not properly clothed, and they are supplying the need as best they can from their own funds. They are not giving unintelligently. Each case is investigated by the school nurse at the request of the teacher. Deserving and eligible cases are referred to the Community Chest or the County Welfare Department. But the available aid is frequently not adequate.

Then the school steps in, supplying things that are needed, through teachers, personal contributions, P. T. A. or Student Body funds—in any event supplying the need.

. . . A careful study of the effect of the current depression on child health and welfare is badly needed. Lacking an exact statement, however, we may rely on the reports of competent social workers and upon studies of child welfare made in previous depressions.

The evidence from the latter source is perhaps best represented by a study of unemployment and child welfare conducted during the industrial depression of 1921–1922.

The study attempted to show, as nearly as possible, a cross-section of conditions in the families of unemployed men in two cities in which wages had been high. Some of the conclusions follow:

1. *Lowered standard of living*—Half of the families from which complete information was secured spent for their maintenance during unemployment only one-half as much as while the father was working. "The children are drinking tea and coffee instead of milk," was a common report. Frugality in food, even to the point of actual privation, a dangerous saving of fuel, economy in clothing and household supplies, reduction of the housing cost through seeking cheaper quarters or crowding the family to secure an income from lodgers are among the results of unemployment.

2. *Employment of the mother*—Almost one-third of the mothers in the families of unemployed men were gainfully employed. Many other mothers were seeking work. Three-fourths of the working mothers were employed away from home. The absence of the mother or her pre-occupation with gainful work at home meant loss of care, protection, and supervision for the children. They went to school with insufficient breakfast, their clothing was not cared for, and they suffered ill-effects mentally and physically.

3. *Employment of children*—In one-fifth of the families studied children's earnings were a source of maintenance during the father's unemployment. Factory and clerical work claimed the larger proportion of these children. Even while fathers and mothers were most desperately seeking employment some children were leaving school and securing work.

4. *Loss of savings and accumulation of debt*—Savings of a large majority of the families studied were swept away during the period of unemployment. Patiently accumulated funds for the advanced education of the children went along with the rest. Homes and other property were lost through inability to meet payment of taxes. Insurance

funds were allowed to lapse because no money was available to pay the premiums. Many of the families were heavily in debt and felt that father, mother, and children would all have to work as soon as they could find any kind of a job.

Reports compiled by the National Organization for Public Health Nursing indicate that these years of financial depression and unemployment are taking their toll in undernourishment of children. At a health center in New York City, where the percentage of undernourished children has been carefully diagnosed for 3 years, malnutrition has increased from 18 per cent to 60 per cent since 1928. Public health nurses report that their work is handicapped because parents cannot provide their children with the diet recommended. In Louisville, Ky., one agency reports a decrease of 1,000 in the number of children able to meet the health and weight standards.

The importance of stability and security in a child's life can hardly be overestimated. The Children's Charter recognized: "For every child the right to grow up in a family with an adequate standard of living and the security of a stable income as the surest safeguard against social handicaps." That this right of childhood is denied to the children of many unemployed fathers and mothers is well known. A physician has coined the expression "epidemic demoralization," to describe the sense of despair and uncertainty which descends on those who must live by the charity of others. Children share in the loss of security and feel it fully as keenly as adults. A child who discovers that his father is out of a job, that the rent is due, and that no one knows where to get money for groceries has lost that sense of protection that should surround him at all times. The personality and character of such a child may suffer permanent scars from these experiences. Even if he escapes permanent injury the child needs an unusual amount of skilled and sympathetic treatment at school. Under such conditions the school must become much more than an instructional center. It must be a steadying influence to which the child can confidently turn in time of need.

This rapid review of the forces affecting child welfare during an economic depression suggests a third responsibility of the schools growing out of the depression. The educational forces of the nation face a stirring challenge to render an increasingly effective educational service to childhood. All the evidence emphasizes the conclusion: American children need very good schools now more urgently than ever before.

## PUBLIC HEALTH NURSING\*

**The Nurse in Industry**—One of the duties of the nurse in industry is to increase the efficiency of the employees; this is what her employer, who pays her salary, expects of her. Her commonest task is to assist the physician in making his examinations, in giving first aid, and in rendering after-care to injuries which are not serious enough to put the employee off the job. The physician is guide and the nurse is responsible to him for whatever she does under his orders.

The nurse will also be required to render emergency first-aid, and she must know that dressings and the administration of drugs for minor illness are not first aid, which in its simplest terms is "usually the control of hemorrhage, protection against infection other than what has already occurred, and just simple measures as may be indicated to prevent further injury."

The nurse may not have authority to remedy unfavorable sanitary conditions in the industrial plant, but she should use what influence she has with the management if she sees inadequate toilet and washing facilities or their improper condition, improper lighting, ventilation, etc.

In many cases a nurse is employed in an industry which has no safety department. Then it is her duty to assist superintendents and foremen to prevent accidents by attention to safety devices; or if there are none, to try to waken the management to responsibilities in this matter.

The industrial nurse has a fine opportunity to be a real health educator among the employees, who are likely to be little read people, not reached by

adult health education through newspapers, magazines, etc. She can encourage them to bring their health problems to the plant physician or to her instead of going to the neighbor, corner druggist, or cult healer.

By careful example and precept she can protect the employee against accident and injury, thus serving both the employer and the employee.

The industrial nurse owes it to her profession to maintain high ethical standards, and this is not so easy when one considers that it is her job to see that the injured employee returns to work as soon as possible for the sake of the employer and yet does not return before he is able for his own sake.

She needs to be a member of her district and state nurses' association to get the advantages of professional unity. She must also keep in close touch and coöperation with the medical profession and public health profession in the community.

The nurse in industry is most useful if she remains within her own province and does not yield to pressure in prescribing or dispensing treatment for headache, indigestion, menstrual disturbances and the like, which are problems for the doctor.

Finally, it should be emphasized that the industrial nurse is, in the larger sense, a public health nurse as much as the school nurse or the health department nurse. She has a more restricted field but a peculiarly fertile field. She may reach the father of a family in which the health department can have contact only with the mother, or perhaps she reaches the mother of a family, where both parents are working, and the health department never sees any member excepting the children. She has a rich opportunity for selling the ideas of immunization against diphtheria and smallpox, for explaining the necessity of correcting physical defects in school children, and for

\* Please send printed matter or other material relating to public health nursing to Eva F. MacDowall, State House Annex, Indianapolis, Ind.

explaining and furthering the periodic physical examination for adults. She has a magnificent opportunity to be an educator. It is for her to say whether she will use it or let it slip. If she does not elect to use it, then she need not be surprised if she fails to attain her full usefulness and becomes merely a routine swabber of iodine and swather of bandages.—

W. W. Bauer, M.D., *The Nurse in Industry*, *T. Nurse & Hosp. Rev.*, June, 1932, pp. 698-699.

**How a Public Health Nurse Can Prepare for Her Successor**—All too often a departing public health nurse does not leave her office or supplies in such a condition as to enable the nurse who follows her to take up the work with understanding and the least amount of trouble. The American Red Cross Public Health Nursing Service gives the following directions to its nurses for preparing for their successors, which ought to be useful to all public health nurses:

I. A list of where things are in the office should be made. A few of the most important things a new nurse will want to locate as soon as she arrives are:

1. Programs of work for the current year and for several years previous. (If there have been no written programs, the departing nurse would facilitate the work of the new nurse by listing her routine work and special activities and projects she would have been conducting if she had remained.) A brief statement might be attached of possible lines of growth and development for the services, *i.e.*, new projects.
2. Annual Reports
3. Monthly Reports
4. Reports of Committee Meetings
5. Special Reports
6. Location of Red Cross pamphlets, special literature, etc.
7. Location of desk equipment supplies—pens, pencils, paper, ink, etc.
8. Names and addresses of important people: Chapter chairman, Chapter secretary, nursing activities committee chairman and members of nursing activities committee, superintendent of schools, town physicians, president of the local medical society, president parent-teacher association, secretary

local Red Cross committee, chairman teachers' committee, Red Cross nursing and general field representatives, other nurses working in the community, cleaning woman, etc.

9. Home Hygiene class rolls and informational material
10. Inventory of equipment
11. Check list of Red Cross publications and see that those her successor will need are on file.
- II. A description of the filing system used should be prepared if it is not perfectly obvious. To illustrate: If the pupils' records are filed in the school and not in the central office, a new nurse might want to know where to find the pupils' cards.
- III. A month's supply of report and record forms, etc., should be on hand.
- IV. A month's supply of equipment for the nurse's bag (if this is used) should be on hand. This bag should be freshly equipped if the new nurse is coming immediately.

The most important thing, after all, is to leave directions concerning the set-up of the office so that the new nurse will be able to find things. This implies that a nurse before leaving should go over her files, reports, etc., destroying material which is obsolete, and putting what remains in order. Listing, then, will be an easy matter.

After the above has been accomplished, it would be advisable to clear with the chairman of the nursing activities committee and provide her with a copy of the information which has been prepared.—

*How the Departing Nurse Can Prepare for Her Successor*, American Red Cross, N. H. 488 (Aug.), 1931.

Mathilde S. Kuhlman—Mathilde S. Kuhlman, R.N., director of the Division of Public Health Nursing, New York State Department of Health, and one of the pioneers in public health nursing in this country, died suddenly in Albany, May 30.

She first served as tuberculosis nurse in Lockport, N. Y., then as Cortland County tuberculosis nurse. In 1918, Dr. Herman M. Biggs called upon her to assist in mobilizing nursing care in the influenza epidemic of that year. Later she was appointed state super-

visor of tuberculosis nursing, and finally in August, 1920, became director of the Division of Public Health Nursing. At this time there were 8 field nurses under her direction in New York State; at the time of her death there were 73.

Miss Kuhlman was a member of the American Nurses' Association and of the National League of Nursing Education. She was a Fellow of the American Public Health Association and a former president of the New York State Organization for Public Health Nursing.—Mathilde S. Kuhlman, *Health News*, New York State Dept. of Health, IX, 23:95 (June 6), 1932.

**The Second Grading of Nursing Schools Is in Progress**—The results of the second grading of the accredited nursing schools of the United States are coming in and are showing decided improvements over the results of the first grading 3 years ago. Seventy per cent of the 1,458 accredited schools took part in the first grading; 80 per cent of the schools are taking part in the second grading.

A few of the improvements shown in the second grading over the first are:

An increase in number of hours of theory planned for students.

An increase in amount of vacation granted students.

An increase in proportion of students having had four years of high school.

An increase in schools having a full-time instructor and also of those having two or more instructors.

There is a tendency towards doing away

with student allowances, but not an equally strong tendency toward using the money saved for the benefit of the nursing schools.—

*A. N. A. Bull.*, American Nurses' Assn., July, 1932.

**Notice to Nurses**—The undersigned Nominating Committee of the Public Health Nursing Section desires the coöperation of all of its members in canvassing the section for officers and council members for 1932. The offices to be filled are: Chairman, Vice-Chairman, Secretary, and two members of the Council. One member is to fill the vacancy made by the death of Miss Kuhlman.

Only Fellows of the Association are eligible to the Council. The Committee will be most grateful for the submission of possible nominees.

## EDUCATION AND PUBLICITY\*

*It is worth while to stop for a moment to review critically the work done and the methods employed. Such a critical review has proved necessary and fruitful in every science, for the investigator, submerged in daily routine, easily loses his judgment and is inclined to fall into a rut, uncritically employing highly developed and specialized methods in the treatment of cases which are different.—*  
Franz Alexander.

Or, in the treatment of publicity and education situations which are different—different in the varying types of mind, social conditions, occupations, and what not.

Will not vacation be all the more refreshing and stimulating if a portion of it is devoted to a critical review of "the work done and the methods employed"?

**They Will Attend the Institute—**Responses came to the first brief mention of the Health Education Institute announced in connection with the A.P.H.A. meeting in October.

Probably the fuller description in last month's *Journal* and the attractive folder will bring a full enrollment. If you failed to receive the folder please write Mrs. Willimina Rayne Walsh, American Public Health Association, 450 7th Ave., New York.

**Whatever Others Would Like to See—**Samples of any forms of health education or publicity materials of interest to other health workers are wanted for the headquarters of the Public Health Education Section at Washington in October, 1932. Send 2 or 3 copies, if available. Send copies (even

if copies have already been sent to New York) to Washington Display, Evart G. Routzahn, 130 East 22d St., New York.

**Consultation at Washington—**Individual and group consultations will be emphasized at Washington in October. What do you wish to get at Washington? What question do you wish to have answered? What would you like to talk over with several interested people? What have you to tell others? Please write to the secretary of the Public Health Education Section, Raymond S. Patterson, John Hancock Mutual Life Insurance Company, Boston.

**Cutting Costs Display—**How to get the most from the public health dollar invested in public health education and interpretation of the public health department or association will be the subject of a special display at the Washington headquarters of the Public Health Education Section. *What have you to offer? What would you like to see?*

**Exhibit of American Medical Association—**The scientific exhibit of the A. M. A. held in New Orleans, May 9-13, 1932, eclipsed in interest, in the opinion of one visitor, the rich program of papers and discussions. All of the exhibits were worthy of study and most of them were attractive eye-catchers. Considering that doctors cherish the reputation of shunning display, the showmanship evidenced was extraordinary.

Demonstration and action were aptly used. How the respirator works was shown with an actual patient in the cabinet. A clicking photo-electric cell

\* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

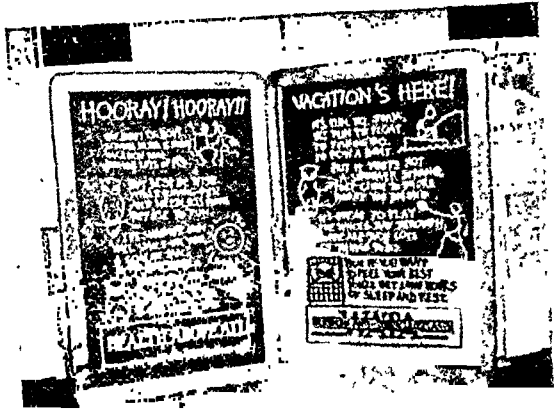

told the story of how ultra-violet rays penetrate or fail to penetrate certain glasses and fabrics, samples of which were at hand. An exhibit of a new fungoid disease of the lungs was "dressed up" with slabs of the maple trees, under the bark of which the offending fungus is found. One exhibit that required detailed study displayed a neat sign inviting the visitor to have a seat facing the display and stating that he would not be bothered by the explainer. The cancer exhibit was made up of a number of units borrowed for the purpose from a number of institutions and research workers.

The physical arrangements were a credit to the Exhibit Committee, being of uniform design, pleasing color scheme, and each bearing a sign stating what the exhibit was about and the name of the exhibitor.—H. E. Kleinschmidt, M.D.

**An Exhibit Idea for the Fair**—The Wisconsin Tuberculosis Association has attracted much attention through the use of crudely chalked messages on an old fashioned double slate. An especially timely use of it was an illustrated vacation message to put out at the time the schools closed. The text and amusing illustrations are shown in the illustration on this page.

The double slate is suitable for a window exhibit or for a permanent place in an exhibit booth. The dimensions are about 6' x 8' and the 4" wide pine frame is bound with red flannel around which colored yarn has been wound. The blackboard panels are made of wall board painted with ordinary black paint, and the writing is done with ordinary chalk. The two frames are hinged together in the center so that the exhibit folds with the writing on the inside, but since the black panels are not flush with the frame the writing does not rub together.

The slate could be used at the opening

of school in September for messages about starting the school year right. The slate idea is adaptable for many uses, for both children and adults.—M. S. R.

**What Survey Reports Say About Health Education**—Dr. Allen W. Freeman has made "A Survey of Health Organization and Service" of Ontario and Columbia Counties, N. Y. The two published reports have been issued by State Charities Aid Association, 105 E. 22d St., New York.

As to Ontario County:

Health education in Ontario County is being actively prosecuted by the school authorities and the County Tuberculosis and Health Association. The addition of a program of adult health education and a better coördination of child health education is a necessary part of the future development of public health in the county.

In Columbia County it is said that

Health education, particularly the education of adults, in the simple truths of hygiene, sanitation and disease prevention, can be attained only by continuous and prolonged effort. But little has been done in this direction up to this time, and the county health department must interest itself largely in the matter. Better coöperation with the school authorities should result also in an improvement in health teaching in the schools.

"Health Education" in the table of contents, Columbia report, refers to health education in the schools.

The opening chapter of each report,

"General Recommendations," from which the quotations came, is the most important of all. Closer reading, and easier use as a check-list of steps to be taken would be gained by the use of sub-headings, and possibly some bold face type to indicate the points made by the author.

**What Shall We Tell the Public?**—What can be said for the continued maintenance of essential services, public and private? Answers to these questions are being sought by a committee of public health workers under the chairmanship of Dr. H. E. Kleinschmidt. What can be said, and said convincingly, with supporting statistics and other data is being assembled to be made available to health agencies in all parts of the country.

This committee is one section of the Committee on Educational Materials, Mrs. Mary Swain Routzahn, chairman, representing the major groups of welfare activities. Some of the assembled material will be made available to community chests for their fall and winter money raising campaigns. Much of it will be utilized in magazine articles, some of which have been arranged for already.

**Health Education in Baltimore**—A very concise survey report gives an outline of health education:

The educational work of nonofficial agencies along the lines of their special interests has been exceedingly valuable. The same may be said of the educational work of certain industrial and insurance companies. The response which Baltimore Division of Chemistry and Food has had in its work with the dairy industry is most encouraging. The plan should be extended to other industries whose products have a direct bearing on health. The possibilities of educational work through civic, social, and professional organizations have scarcely been touched. Mothers attending infant hygiene centers appear to have a good understanding of child care but the response to the school program indicates that more intensive educational work

should be done with parents of these children. The venereal disease clinics are not used as educational centers to any great extent.—A Study of Health and Hospital Service of Baltimore, Maryland, by Joseph W. Mountin, Surg., U. S. Public Health Service, June 9, 1932.

Now that the revised edition of *Community Health Organization* is out it will be easily possible for survey reports to offer constructive suggestions and a source of further information on health education.

**If We Told All**—Just suppose that public health workers generally helped to assemble the data on "what to tell the public." What a wealth of ideas and information could be made available to all who would use the material. A case story, a factual statement, statistical data, an argument, a paragraph from a report, a book, an article—any form of material usable in "telling the public" that public health must be maintained will be welcome. Address the chairman of the Health Section of the Committee on Educational Material, Dr. H. E. Kleinschmidt, or the Section secretary, Thomas C. Edwards, National Health Council—both at 450 7th Ave., New York.

**Local Health Education Councils**—The sharing of plans and programs, and the discussion of common problems in health education were never more important than at present. Increased effectiveness at even lower costs may be expected to result from conference between local workers.

There could be an independent Health Education Committee or Council wherever 3 or 4 or more local groups are doing something in health education. Where there is a Public Health Council there might be a committee on health education which would bring together, 6 or 8 times a year, representatives of all the local groups concerned. The local Social Work Publicity Council

might well have a health education committee.

Where there is no S.W.P.C., those doing health education could join with the publicity workers in starting such a council for the joint study of many problems in technic, and then hold their separate health education sessions.

A list of topics for health education councils or committees, and plans for a social work publicity council will be supplied upon request to Social Work Publicity Council, 130 E. 22d St., New York.

Whatever the plan followed the arrangement should be simple and be free from organization red tape. A committee of 2 or 3, a mailing list, and a determination to give and get ideas and information are the essentials.

See "Your Libraries May Have the Book," in this issue for one job for such a committee or council.

**Your Libraries May Have the Books**—Almost any book remotely touching the field of this department contains information or will stimulate ideas for use in the education and publicity work of department or association. The many which are beyond the budget limit of the worker in education will usually be found in the local public or university library, or will be supplied by the state library or library commission.

The more we ask libraries for such books the more likely we will be able to get them. Whenever a book is not in the library, a letter of request or suggestion may be sent to the librarian. Others in health or social work may be enlisted to ask for the same books.

**Conservative Modernism in a Report**—Attractiveness and readability with dignity characterize the 49th annual report of New York Post-Graduate Medical School and Hospital. The modernism in typography and layout

provide distinction without gymnastics in graphic form. Photographs "bleed" over the upper and outer edges of the page, with white space near the opposite edges. Sketches, without captions, illuminate chapter endings *but never appear opposite a photograph*. The running heads at top of pages facilitate location of contents, supplementing an adequate table of contents, which is not labeled "Contents." Two pages about "Living Memorials" emphasize

. . . a growing belief among thoughtful people that memorials should be vital and emblematic of service rather than mere monuments of granite.

The end-papers express an interesting idea for making graphic the details of out-patient service, but its effect is confused by the banners for the display of the legends. Picture maps need to be extremely simple to be clear and readable.

Most of the distinctive elements in the report are adaptable to other reports, without taking over the two or three details which may seem expensive, such as the heavy cover, and the end-papers. Sample, 20 cents.

**Is This a Fair Check of Your Radio Audience?**—K. W. Grimley, Bureau of Health Education and Publicity, Jefferson County Board of Health, Birmingham, writes about "Checking The Radio Audience" in this department Feb., 1932:

An interesting article, and a ditto idea: but open to the objection of inflicting another questionnaire upon an already murmurous population; a course which I personally do not care to risk.

We have been trying to get a line on our radio audience (we present one talk per week, 10:45 A.M. Tuesdays, over WAPI, locally owned NBC affiliate) by having the announcer, after the talk has been given, conclude with the words: "copy of this lecture will be sent to anyone wishing it. Just write

or telephone your request to the Jefferson County Board of Health, Birmingham."

Over the past 3 months, during which we have presented about 12 lectures, we have received approximately 50 requests. If, as the broadcasting people claim, only a small fraction of 1 per cent ever write in for anything, we are getting a fairly good audience. If not, we're wasting about \$15 a week, as that's how much it costs in time to prepare a talk.

Of the total requests "Diabetes" drew 26 per cent; "Care Of The Teeth," and "Cancer" each 15 per cent (about cancer: "We paid good money to advertise this talk in all 3 of our daily papers"); "Diphtheria," not a single request. Mr. Grimley scored his talks as to "the actual composition and diction in comparison with each other." "Diphtheria" and two others were "bad," but several scored as "good" drew but 3 per cent each of the responses.

Was that a good check on the audience? Might the response be different if "additional information" or "answers to questions," had been offered, or "instructions as to what you should do about so and so," or the offer of a pamphlet or folder?

We hope that Birmingham will experiment with various offers and report the results.

#### RADIO

Some of the possibilities in handling topics are illustrated by the opening paragraphs from broadcasts by the Illinois State Dept. of Health:

Americans take about 3,000,000 gallons of cod liver oil a year. If one figured this out in teaspoon doses it would be like figuring the number of miles the sun is from the earth. Why do we take so much cod liver oil? The leading producer of cod liver oil is Norway, and then come Newfoundland and the United Kingdom. We take most all of the cod liver oil produced by these countries as well as come from Japan. We are the world's leaders in cod liver oil consumption.

The best time to treat a cold is to start at the time you feel chilly, when your nose begins to swell and you start sneezing. Like static in your radio or carbon on the auto cylinders,

you are out of adjustment and your involuntary controlling system is upset. Your skin is pale and cold, you feel chilly even in a warm room with an overcoat or fur wraps. The blood vessels in the skin are contracted, your temperature is below normal. The nose and eyes are red, your head feels full and you have a headache.

Man is a porous sack of water. Through his millions of perspiration glands, miles of ducts, lungs and kidneys he loses about 3 quarts of water daily. This must be immediately and continuously replaced and hence he is compelled to live near an inexhaustible supply. Since his very existence depends upon water, it thus carries equal powers of destruction to his welfare and health. Thus it is imperative that man devise means of controlling and preventing this destruction.

From Connecticut Dept. of Health come two radio dialogues, in one a layman and a public health official talk over smallpox vaccination; in the other a mother and a physician discuss the services of the laboratory to physicians. The second one has fewer technical terms. "Is the Can Opener a Cause for Divorce?" a monologue, and "Fat Mothers and Thin Children," a playlet, presented by Elizabeth C. Nickerson with the aid of staff members as Mrs. Jones, Mrs. Black, and other characters. *Frec.*

#### Health News reports:

A radio health talk on goiter, one of the series broadcast weekly by the New York State Department of Health through the courtesy of WGY, was heard over W2XAF, the short-wave experimental station of the General Electric Company, by a merchant in Playa-Ponce, Porto Rico.

The manager of an American copper plant in Chile heard over the same station, the recent talk on "How the State Department of Health Protects Your Milk Supply" and requested further information about the laboratory control of milk pasteurizing plants.

The United States minister to Bolivia, a former classmate of C. A. Holmquist, director, Division of Sanitation, wrote from La Paz that he had listened to the latter's talk on "The Sanitation of Our Surroundings—A Governmental Function" broadcast from station W2XAF on February 24.

"Broadcast to men—women reply," says *Illinois Health Messenger*:

On October 31 the regular weekly broadcast of the Illinois State Department of Public Health, given over WGN at 11:50 A.M., was directed especially to the business man. The title was, Keeping Fit for the Ten to Two Load in Business.

It proved to be particularly popular—but not among men. Eight out of each ten letters asking for copies of the address were from women. Most of them were signed with the prefix "Mrs." however.

The New York City broadcasting in the Early Diagnosis Campaign was a joint project of the New York Tuberculosis and Health Assn. and the New York Academy of Medicine. Ten stations carried 58 talks between March 23 and April 27. Nation-wide hook-ups carried 6 of the talks, with the addition of associated network stations for 6 others.

#### CUTTING COSTS

Probably we all know what pamphlets of 24 or more pages (of which 22 pages must carry some form of printing) go as 3d class at book rate of 1 cent for each 2 ounces or fractions thereof (not more than 8 ounces). Covers count as pages.

By filling out the special permit form, printed matter mailed in lots of 200 or more identical pieces (or totalling 20 pounds or more in weight) will cost 12 cents a pound (or not less than 1 cent for each piece). Pamphlets (described above) will be accepted under this bulk permit arrangement at 8 cents a pound or 1 cent minimum. Secure form at Post Office.

By filling out the permit form at the local post office, unsealed circular or form letters (printed, mimeographed or multigraphed) may be mailed in lots of 200 or more identical copies at 12 cents a pound or 1 cent minimum.

*Without a permit* unsealed circular or form letters, or other mimeographed or multigraphed material may be mailed in lots of 20 or more identical copies at 1½ cents minimum.

The following may be written by hand or typewriter on the circular or form letter: date, name of addressee, name of sender, salutation or ending such as "Dear Sir" or "Sincerely yours."

Under the permit arrangement the mail must be sorted, tied, and marked whenever more than 15 pieces go to a city or state.

*In all cases consult your local post office.* In case of any confusion or difficulty growing out of the complicated regulations, explain your problem to *Postage and The Mailbag*, 200 5th Ave., New York, enclosing 3 cent postage stamp.

Also address *Postage and The Mailbag* if you wish a summary of postal rates and regulations for 1st and 3d class mail.

A variety of valuable articles on cutting costs and on making better use of the mails is offered in the June-July, 1932, issue of *Postage and The Mailbag*. If the two articles on the use of postal cards results in but a single mailing of cards in place of something more expensive one will save many times the 25 cent cost of that issue of the magazine.

## BOOKS AND REPORTS

*The Mental Defective*—By *Richard J. Berry, M.D., F.R.C.S., F.R.S.E., and R. G. Gordon, M.D., D.S.C., F.R.C.P.E.* New York: McGraw-Hill, 1931. 225 pp. Price, \$2.50.

This volume divides itself rather distinctly into two parts. The first part, with the exception of the first chapter, has to do almost entirely with the anatomy and physiology of the central nervous system but especially the brain. Approximately 60 per cent of the book is concerned with the latter.

To the nurse or social worker interested in the practical aspects of caring for the feeble-minded, this volume offers little or nothing new. On the other hand, it contains many very interesting statements, e.g., the authors quote a study made of the inmates of an Illinois girls' reformatory where it was found that 97 per cent of these girls were feeble-minded. The reviewer wonders if the percentage of feeble-minded in any school for the feeble-minded is any higher than this. A study is also quoted which shows that two-thirds of the feeble-minded fell within the microcephalic group; another study that showed that two-thirds of the feeble-minded were below par physically; in a study made in Australia it was found that 80 per cent of 355 criminals studied were microcephalic. Another very interesting statement, which appears on page 179, is as follows:

No matter what the social standing or status of the individual, an addiction to drugs or a chronic alcoholism is, of itself, very frequently pathognomonic of mental deficiency. Again, it is not usually the drugs and the alcohol which produce the deficiency but the defect that induces the habits.

The above statements, we believe, are wholly inconsistent with the results ob-

tained from similar group studies in this country.

This book has value for the physician who is interested in obtaining a practical understanding of the anatomy and physiology of the nervous system as found in the mental defective. However, the discussions of some factors, e.g., the rôle played by the special senses in the mental life of the mental defective, in view of their practical importance, seem to be unnecessarily lengthy.

The authors of this volume have attempted to treat authoritatively, too much from a neurological point of view, a subject that is primarily, on the practical side, a psychological and social one.

The book is very well written and easily read. It consists of 8 chapters and an index and contains 225 pages. There is no bibliography.

FRANK J. O'BRIEN

*Health and Its Maintenance. A Hygiene Text for Women*—By *Bertha S. Dymont, M.D.* Stanford University, Calif.: Stanford University Press, 1931. 472 pp. Price, \$3.50.

This textbook contains as much anatomy and physiology as is considered essential in the rationalizing of instruction in hygiene. It is designed primarily for those who take a course in hygiene before physiology and anatomy have been studied.

The various systems of the body are presented in separate chapters, each one including its physiology, some of the most common diseases, and the hygiene. One chapter, "Individual Mental Hygiene," is written by Catherine Cox Miles. Another chapter, "The Girl

About to Marry," is by Mrs. Eric Allen. The last three chapters of the book are devoted to embryological development, heredity, and dieting.

The book is written in an interesting style. It is sufficiently concise to permit assimilation of its content by students. If, as the author suggests, the text material is supplemented by the use of slides, models, and demonstrations, it should prove a successful book. It would be an even more valuable text if it had included a chapter on immunity, infection, and modes of transmission of disease.

ESTHER W. STEARN

**Sanitary Law in Question and Answer—***By Charles Porter, M.D. and James Fenton, M.D. 3rd ed. London: H. K. Lewis & Co., Ltd., 1932. Price 21s.*

The fact that this book has gone through three editions is evidence of its value to those for whom it is particularly intended; namely, students in public health sanitary law. As is stated in the preface, the subject presents great difficulty, partly on account of the enormous number of laws, additions, alterations in methods, amendments, etc.

It is hard for an American to review a book of this type, as England is far ahead of us, not only in laws, but in their observance. We can say without hesitation, however, that no man in England is better fitted to deal with this subject than Dr. Charles Porter, who is a barrister-at-law as well as a Medical Officer of Health, and in this edition he is assisted also by Dr. Fenton, Medical Officer of Health of the Royal Borough of Kensington.

The book appears to cover in a clear and concise manner every question that the student can ask. Unfortunately, it is not directly adapted to American readers, except that all of us can learn much from the English, to whom we

owe the great sanitary awakening under Chadwick. The book is well printed and made up. MAZÏCK P. RAVENEL

**Control of Conception—***By Robert Latou Dickinson and Louise Stevens Bryant. Baltimore: Williams & Wilkins, 1931. 290 pp. Price, \$4.50.*

**The Practice of Contraception—***An International Symposium and Survey—Edited by Margaret Sanger and Hannah M. Stone. Baltimore: Williams & Wilkins, 1931. 316 pp. Price \$4.00.*

For many years the advocates of birth control in this country have endured slurs, insults, and imprisonment, in their bitter struggle for what they hold to be one of the most vital problems affecting the happiness of the home, and the economic welfare of future generations. There is little doubt that many persons who believe that the subject is worthy of careful consideration would have come out openly for it except that the remedies proposed in the past have not seemed adequate or properly controlled, and that the subject offends several of our important religious bodies. The matter is still in a controversial stage, but it seems much better for it to be in the hands of educated and earnest people than in those of the insincere and the charlatans. For this reason we believe that the review of these books has a place in this JOURNAL, which has up to the present time avoided the subject for the reasons given above.

As a result of these efforts, this problem is receiving widespread attention. It is discussed in the open forum of the current journals and magazines, it is debated in the highest ecclesiastical circles, and receives the thoughtful consideration of legislative bodies.

Whatever opinion one may have held of the necessity or desirability of giving the general public information for the prevention of conception, it is necessary to recognize the fact that this question

can no longer be ignored, and that the claims of its sponsors must be examined fairly and critically.

No adequate presentation of the subject, summarizing the opinions of the leaders in various countries throughout the world, and offering for critical consideration the accepted methods and the results thus far achieved, has been available until recently. It is true that several small publications have been on the market. Some of these are obviously pornographic. Others have been written entirely for the individual directly interested in preventing a possible pregnancy. However, the appearance of the two volumes, *Control of Conception* and *The Practice of Contraception*, has completely satisfied this need. These books are to be recommended without reservation to those who are interested in this important problem, whether for or against its further spread. Here will be found a frank discussion of its sociological aspects, a description of the various methods used to prevent conception, and an analysis of the results obtainable.

The *Control of Conception* is a book which should be of great value to social workers and to physicians alike. The simple straightforward language required no small amount of courage on the part of the authors. Anatomy and the physiology of fertilization are fully described and well illustrated. The known and commonly used methods for prevention are given in detail and evaluated. Operative measures for sterilization and abortion are adequately described. The last chapters are devoted to the organization and administration of birth control clinics, and a discussion of the present laws of various states and the federal government.

The *Practice of Contraception* is a complete report of the proceedings of the 7th International Birth Control Conference, Zurich, September, 1930. Reports on contraceptive methods em-

ployed were made by members for the United States, Germany, Russia, Austria, Holland, Denmark, India, China and Japan. Of particular interest is the report from Russia by Dr. Martha Ruben-Wolf.

One cannot read these books without realizing the social importance of this subject and the earnestness of its advocates. The authors have performed a much needed service and have done it well.

D. L. HARRIS

*Principles and Practices in Public Health Nursing Including Cost Analysis—Prepared by The National Organization for Public Health Nursing. New York: Macmillan, 1932. 129 pp. Price, \$1.75.*

This book is published just at a time when public health nursing agencies need guidance in showing to a scrutinizing public the relation of cost to quality of service. Therefore it is of double value. "It has been prepared especially for the guidance of executives and board members, that they may compute the cost of a visit and that they may maintain a standard of service consistent with the best public health and medical practice." It is aimed to supplement and to be used in connection with the *Manual for Public Health Nursing and The Board Members' Manual*.

The first part of the book discusses principles and accepted practices which are definitely related to cost. It discusses, among other things, personnel, salaries, health of staff, supervision, educational programs, working hours, visits, transportation and records and reports.

The reports of the Service Evaluation Committee and other special committees, the findings of time and activity studies of public health nursing organizations and reports and recommendations of the various committees of the National Organization for Public

Health Nursing which have been published at times in *Public Health Nursing*, have been drawn upon for the first part of this book. This contains the latest and best known in public health nursing procedure in brief, concise and usable form. The second part of the book deals with detailed directions for computing the cost of a visit.

While the nurse working alone might find the book helpful in computing the cost of a visit, it will not mean as much to her as to the organizations employing more nurses. To them it would be indispensable. It has been compiled with these larger organizations in mind.

The directions for computing the cost of a visit show that more work needs to be done to help those organizations who are giving a generalized service including school nursing. In their services the distinction between what is and what is not related to a nursing visit is so difficult to make that an unfair computation of cost often results.

For the organizations who are anxious to appraise themselves as to quality of service in relation to cost, for those who want to determine upon a fair charge to individuals who are able and want to pay for the service, and especially for those who have contractual agreements with other agencies for service on a cost basis, this book is a necessity.

The book is small, only 129 pages, well bound, easy to read, and well indexed. The appendix contains reports of the N.O.P.H.N. Service Evaluation Committee and the Records Committee—also suggested forms for use in calculating costs. VIRGINIA A. JONES

**Oxford Medical Adviser for the Home**—By John D. Comrie, M.D.  
New York: Oxford University Press, 1931. 391 pp. Price, \$2.25.

This volume has been prepared for use in the home. It purports to give advice of a practical character pertain-

ing to the preservation and restoration of health. Unfortunately for those who are expected to derive benefit from this source, things are included which are not of general interest, and others are not included which would enable the individual to detect early signs of disease. Although written for the laity, there is little justification for generalizations to be at variance with fact, as is so apparent in the sections on cretinism and ptomaine poisoning.

It is a nice question as to whether such books as this have a place. For people living in rural sections at great distances from medical help, they are undoubtedly of service at times. On the other hand, combined with the unscrupulous claims of patent medicine advertisers and the fact that many such medicines are sold at every crossroads store, the advice given is apt to lead many people to too much self-medication. NEWELL R. ZIEGLER.

**How to Interview**—By Walter Van Dyke Bingham and Bruce Victor Moore. Harper, 1931. 320 pp. Price, \$4.00.

The book aims to bring together from every field what it can to add to our general knowledge of how to interview, and also the peculiar technics of each field with a view to arriving at that definite plan and systematizing necessary in the interview that will yield results, and it has done so exhaustively and most admirably.

Chapters two and three are of great practical value. Chapter two is devoted to "systematizing the vocational interview." While dealing with the vocational field it is essentially a basic pattern which can be used by all interviewers regardless of their fields. The differences in details and emphasis are shown in the specific technics used in the interview for legal evidence, in journalism, in the mental clinic, in education, in social case work, in industrial

relations, and in employment—all simply and interestingly given.

Chapter three presents excellent, very practical suggestions to those "learning how to interview." The same chapter studied by those long used to interviewing could well serve as a standard for self appraisal.

Part II is concerned with "Researches in the Use of Interviews for Industrial Fact Finding." One experiment is to discover the attitudes of employees toward an employment guarantee plan, another in interviewing textile workers on strike. Both research experiments aimed to show "the proper uses, reliability, and technics of the interview process." They did show that it has its proper uses, the chief of these is "in ascertaining knowledge, not about external physical facts and events but about an interviewer's attitudes and feelings." "This is the area in which the interview as a fact-finding instrument has its greatest value." This is very fortunate because it is concerning such that "records and similar objective sources are least available."

The bibliography on the personal interview, assembled by Dr. Moore, is a comprehensive survey of the literature in English. It alone is worth the price of the book.

GRACE ROSS

**Diabetes and Its Treatment by Insulin and Diet—By Orlando H. Petty, M.D. 5th ed. Philadelphia: Davis, 1931. 224 pp. Price, \$2.00.**

In the successful handling of patients suffering from diabetes mellitus, a thorough education of the patient is a most important factor. Handbooks for the patients, written in plain and intelligible language, have become not only a desirable, but an almost indispensable part of the management of this disorder, the proper treatment of which should reduce its present inexcusably high mortality.

The 5th edition of this "Handbook

for the Patient" should be welcomed, therefore, not only by the diabetic patient, but equally by the physician who treats diabetics. It covers practically every problem of the disease and its treatment. Dr. Petty's writing is clear and concise, and can be easily understood by the layman.

The reviewer agrees with Dr. Petty as to the importance of weighing the diet, especially in severe cases. This method has its shortcomings because of impracticability; nor need it be forced upon the intelligent and coöperative patient with milder diabetes.

A very commendable chapter is that dealing with salt-free diet, the value of which is becoming well established. The Jewish patient, following orthodox dietary laws, will welcome a large number of special diet forms. The importance of close coöperation between internist and surgeon in the handling of surgical diabetic cases, has been sufficiently stressed in the preface by the late Dr. Deaver; the necessity of such team work is becoming more and more recognized. Dr. Petty's handbook serves its purpose very well in every respect.

R. SCHARF

**Tests and Measurements—By Irene Palmer. New York: Barnes, 1932. 143 pp. Price, \$2.00.**

This small volume is designed for the use of teachers and students of health and physical education. It is an attempt to interest these individuals in the possibilities of measurement and to give them a basis for evaluation and interpretation of tests.

Eight chapters are devoted to a consideration of very elementary statistics. While this information is useful to some individuals, and is of some interest, anyone who might attempt to draw conclusions with no further knowledge of statistics than this, is likely to fall into error in many instances. This and other parts of the

book are distinctly marred by the reproduction of longhand tables and calculations.

There are three chapters pertaining to public health, one of which includes Dr. Thomas D. Wood's Personal Health Standard and Scale. Other chapters are concerned with tests of motor ability, achievement, and knowledge.

The make-up and quality of paper used in the book is good.

NEWELL R. ZIEGLER

#### Principles of Health Education—By

*Clair E. Turner, Dr.P.H. Boston: Heath, 1932. 317 pp. Price, \$2.00.*

Health education in schools is one of the more recent aspects of the modern public health movement which promises much for the educator, for the health worker, and for the public. But in the words of the superintendent of the Malden, Mass., schools, who prepared the foreword to this volume:

The proper correlation of the numerous and varied health activities now existing in educational systems is a perplexing problem to everyone interested in, or responsible for, the organization and direction of school curricula.

Furthermore, until recently, a satisfactory definition of what is embodied in health education, and the methods of practical health instruction in schools, have been wanting.

Here is a manual for various groups engaged in health education work in schools which has been carefully prepared by an author eminently qualified for such a task. Years of experimenting in this field and in teaching the subject to classroom groups of school administrators, graduate students, teachers, and nurses have paved the way for the crystallization of a wide experience.

The book consists of 15 chapters dealing with the development of the school health program, the definition of and reasons for health education in schools, including underlying principles in health education, curriculum con-

struction, routine procedures, gradation of material, source material, health education in junior and senior high school, the training of teachers and supervisors, and school health administration.

The reliability and use of growth measurements are also discussed. Principles and procedures are set forth which have been found practical and useful, with special reference to the Malden schools. The book is timely, interestingly written, and well printed.

IRA V. HISCOCK

*Rural School Nursing—The American Red Cross, Washington, D. C. 152 pp. Price, \$.50.*

The third revised edition of *Rural School Nursing* is, as formerly, designed for the nurse working alone in a community, usually in a large county where school nursing is only one phase of the public health nursing program, where there is no medical inspector and where there are several thousand pupils to one nurse.

Emphasis is placed on the joint and separate responsibilities of the teacher and the school nurse for the health of the rural child.

This little book was greatly needed among rural school nurses to bring them up to date on some of their practices. It makes a fine supplement for Mary Ella Chayer's *School Nursing*, recently published, which gives the underlying philosophy of all school nursing.

EVA F. MACDOUGALL

*Medical Administration of Teaching Hospitals—By Emmet B. Bay, M.D. Chicago: University of Chicago Press, 1931. 136 pp. Price, \$2.00.*

This book concerns itself with the medical aspects of administration in teaching hospitals, and presents the findings of a comparative study of 19 important teaching institutions in this field.

The foreword, by Michael M. Davis,

not only emphasizes the great need for adequate organization because of the complexity of modern medicine, but stresses the effect of over-specialization upon general efficiency in the field of medicine. Davis emphasizes the outstanding value of Bay's analysis in furnishing the impetus for the promotion of other comparative studies of important hospital functions. Attention is focused, too, upon the period of evolution and experimentation through which medical schools and affiliated hospitals are now passing.

The following are some of the more specific problems presented and discussed: (1) Admission of patients, (2) Keeping of medical records, (3) Relation of the Outpatient Department to the hospital, (4) Administrative duties of the Chief of the Medical Service and of the Resident Physician.

Bay lists a series of very necessary functions and endeavors to show the

methods employed in the performance of the same in the 19 institutions studied. Interesting deductions are presented to the reader who cannot but become acutely aware of the many problems confronting medical administration.

In addition to a brief descriptive summary of the 19 institutions included in the study, the author also presents a chart used for the analysis of administrative functions and outlines particularly the problems existing today and what appears to be the probable solution of them.

The data assembled furnish a well defined set of findings and set up a technic for the study of medical administration for teaching hospitals. Very effective methods for the administration of this type of hospital are presented and the book, as a whole, proves very interesting and readable.

CHARLES F. WILINSKY

## BOOKS RECEIVED

ACCIDENTS, NEUROSES AND COMPENSATION.

By James H. Huddleson and J. Ramsay Hunt. Baltimore: Williams & Wilkins, 1932. 256 pp. Price, \$4.00.

THE CHEMISTRY OF TUBERCULOSIS. 2d ed.

By H. Gideon Wells and Esmond R. Long. Baltimore: Williams & Wilkins, 1932. 481 pp. Price, \$7.00.

HYGIENE. A Textbook for College Students.

2d ed. By Florence L. Meredith. Philadelphia: Blakiston, 1932. 802 pp. Price, \$3.50.

THE SOCIAL AND ETHICAL SIGNIFICANCE OF

NURSING. By Annie W. Goodrich. New York: Macmillan. 401 pp. Price, \$3.00.

THE SCIENCES OF MAN IN THE MAKING. An

Orientation Book. By Edwin A. Kirkpatrick. New York: Harcourt Brace, 1932. 396 pp. Price, \$4.00.

HYGIENE OF COMMUNITY, SCHOOL, AND HOME.

By Ernest W. Steel and Ella G. White. New York: Harper, 1932. 368 pp. Price, \$2.25.

FUNDAMENTALS IN MASSAGE. By Kathryn L.

Jensen. New York: Macmillan, 1932. 167 pp. Price, \$2.00.

TOWARDS NATIONAL HEALTH, OR HEALTH AND HYGIENE IN ENGLAND FROM ROMAN TO VIC-

torian Times. By J. Anthony Delmege. New York: Macmillan, 1932. 234 pp. Price, \$6.00.

Medicine and the State. The Relation Between the Private and Official Practice of Medicine with special reference to Public Health. By Sir Arthur Newsholme. Baltimore: Williams & Wilkins, 1932. 300 pp. Price, \$3.50.

Proceedings of the Ninth Annual Short School Texas Public Health Association. November 9-14, 1931. Austin: Texas Public Health Association, 1932. 84 pp. Price, \$50.

LEAGUE OF NATIONS. QUARTERLY BULLETIN OF THE HEALTH ORGANIZATION. Vol. I, No. 1. Boston: World Peace Foundation, 1932. Price, \$50. Yearly subscription \$2.00.

THE CRITICISM AND IMPROVEMENT OF DIETS. Ministry of Health: Advisory Committee on Nutrition. 1932. 14 pp. Price, \$10.

Health and Home Nursing. By George Margaretta Douglas. New York: Putnam, 1932. 383 pp. Price, \$2.50.

HOUSE DESIGN, CONSTRUCTION AND EQUIPMENT. The President's Conference on Home Building and Home Ownership. Washington, D. C., 1932. 325 pp. Price, \$1.15.

## A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

**Milk Supply Supervision**—This discussion of modern milk sampling practice indicates how vastly more complicated are the milk supply control problems of the great urban centers than are those of the typical small city.

BREW, J. D. Locating the Causes of High Bacteria Counts in Milk. *Municipal Sanitation*, 3, 6:238 (June), 1932.

**Another Venereal Disease Survey**—New Orleans was found, in the survey reported upon, to have a venereal disease incidence lower than that of other cities. But as the proportion of cases treated illegally by others than physicians was found unusually high, the showing will not be viewed with undue pride by the sanitary authorities of the city.

CLARK, T. and USILTON, L. J. Prevalence of Venereal Disease in New Orleans, La. *Pub. Health Rep.* 47, 22:1187 (May), 1932.

**Scarlet Fever Isolation**—The clinical aphorism that a disease with many remedies has none, applies aptly in criticism of present-day control measures for scarlet fever, say these authors who have summarized the seemingly hopeless variety of isolation and quarantine requirements. A logical basis for reasonable regulations is discussed.

DARLING, G. B. and GORDON, J. E. American Administrative Practice in the Control of Scarlet Fever. *J. Prev. Med.* 5, 3:185 (May), 1932.

**Private Practice and Health**—The editor of the *J. A. M. A.* tells whither the private practice of medicine is drifting. Everyone should read this paper not only for what is said but the way in which it is written. Would that other writers in the field of public health could take a leaf from this effort.

FISHBEIN, M. Present-Day Trends of Private

Practice in the United States. *J. A. M. A.* 93, 24:2039 (June 11), 1932.

**Cancer Cures**—So little evidence of cancer cures is ever published that this summary of the experience in the Massachusetts Cancer Clinics is welcome. Such evidence is needed to combat the prevailing attitude toward cancer. As the author says: "When a patient dies of cancer every one knows it; when a patient is cured of cancer few know it and none like to admit it."

GRAVES, W. P. Summary of Cured Cancer Clinics. *New Eng. J. Med.* 206, 25:1302 (June 23), 1932.

**Cod Liver Oil and Milk**—A small group of underweight employed young women were given cod liver oil and milk in addition to their home diets. They gained an average of 2.6 pounds, were absent 195 hours less than during a previous period, and improved their efficiency.

HOLMES, A. D. *et al.* Results of Supplementing the Dietary of Substandard Workers With Cod Liver Oil and Milk. *J. Indust. Hyg.* 14, 6:207 (June), 1932.

**Human Intestinal Parasites**—A state-wide survey in which the feces of 32,000 persons were examined revealed that hookworm infestation had been so reduced in incidence that only in restricted localities in Tennessee was it a menace, but that other intestinal parasites had not been affected. The sanitary and hygienic problems involved are discussed.

KELLER, A. E. *et al.* A State-Wide Study of the Human Intestinal Helminths in Tennessee. *J. Prev. Med.* 5, 3:161 (May), 1932.

**All About Vitamin A**—The story of the research leading to the detection

of vitamin A, the characteristics and pathology of avitaminosis, the assaying and chemistry of the vitamin and its functions, are all included in an excellent summary of this broad subject. The paper is the first of a series on vitamins, all of which should be of great interest to health workers.

MENDEL, L. B. Vitamin A. *J. A. M. A.* 98, 23:1981 (June 4), 1932.

**Abortive Poliomyelitis**—Epidemiologic study of poliomyelitis outbreaks indicates that, accompanying frank cases, there occur many cases of illnesses not unlike incipient poliomyelitis. These minor illnesses occur among contacts more frequently than is commonly supposed, the ratio to orthodox cases being 6 to 1.

PAUL, J. R. *et al.* "Abortive" Poliomyelitis. *J. A. M. A.* 98, 26:2262 (June 25), 1932.

**Educational Opportunities in Dental Clinics**—Small units with affiliated nutritional and educational workers produce very practical returns in health, if the experience in New York

City is typical. A valuable contribution.

SINKS, A. E. Dental Clinics and Education. *Child H. Bull.* 8, 3:81 (May), 1932.

**Health Education Abroad**—Thus concludes a most stimulating discussion on health education problems: "Propaganda is now a legitimate department of preventive medicine. It tries to meet the profound and sometimes pathetic anxiety for a knowledge of health, and by its inadequacy it produces a sad state of enthusiasm." Could a happier phrase than "sad enthusiasm" be chosen to describe the plight of the usual victim of our efforts to educate?

WILLIAMS, J. H. H. Creative Health Propaganda. *J. State Med.* 45, 9:271 (June), 1932.

**A Story of Smallpox**—An illuminating history of smallpox and vaccination in Massachusetts providing valuable statistical references and entertaining excerpts from early writings on the subject. Altogether a most useful source of material for the vaccination propagandist.

WOODWARD, S. B. The Story of Smallpox in Massachusetts. *New Eng. J. Med.* 206, 23:1181 (June 9), 1932.

## NEWS FROM THE FIELD

### U.S.P.H.S. NEW BUILDING

ON May 7 the cornerstone of the new office building for the U. S. Public Health Service in Washington, D. C., was laid by the Secretary of the Treasury. The ceremony was attended by the Assistant Secretary having supervision of the Public Health Service, Surgeon General H. S. Cumming, and a group of other persons interested in the Service.

### ISOLATING DISTEMPER GERM

IN an effort to isolate the distemper germ and to find a serum, experiments are now being carried on in the Welcome Research Laboratories in London. Fifty silver foxes have been shipped to London for experimental purposes by the Canadian National Express, the animals having been selected from the ranches in the vicinity of Moncton, New Brunswick.

### INDIANA CHILD HEALTH INSTITUTE

THE annual Child Health Institute, arranged by the Indiana State Board of Health, was held at the Winona Lake Chautauqua, July 4-9. It was devoted to home protection and to the conservation of the child by the home in coöperation with the community and organized lay groups and professional and official agencies. The specific topics emphasized were: Safety, Sports, Better Homes, Nutrition, The Handicapped Child, Medical Service, Probation Problems.

### PARENT-TEACHER PLANS

PLANS of work and policies for the more than 20,000 parent-teacher associations, units of the National Congress of Parents and Teachers, will

be considered at the meeting of the Parent-Teacher Board of Managers to be held from September 26 to October 1 at the Edgewater Beach Hotel, Chicago.

### WILLIAM WOOD AND WILLIAMS & WILKINS MERGE

THE Williams and Wilkins Company, of Baltimore, on June 16, purchased inventory assets and good will of William Wood and Company, well known as one of the oldest American publishers of medical text books and importers of English medical books, established in 1804 by Samuel Wood. The firm name will be perpetuated, and business will continue for the time being at 156 Fifth Avenue, New York. The Williams and Wilkins Company has always specialized in various research publications, including medical works.

## PERSONALS

DR. GREENE L. REA, member A.P.H.A., has been appointed acting Health Officer of Charlotte, N. C., succeeding Dr. Wilbur A. McPhaul, member A.P.H.A., who recently resigned to become Health Officer of Pensacola, Fla.

DR. JOHN R. TARRANT has been appointed Health Officer of Portland, Conn., succeeding Dr. Donald J. MacGillivray.

DR. THEODORE F. FOSTER has been appointed Health Officer of West Hartford, Conn.

DR. JAMES J. CHARRON has been appointed Health Officer of Putnam, Conn.

DR. WILLIAM J. FRENCH, of New York, has been appointed full-time Health

Officer of Howard County, with headquarters at Ellicott City, Md., and Dr. Robert H. Johnson, of Brookhaven, Miss., is the New Health Officer of Somerset County, with headquarters at Princess Bay, Md. Dr. French, member A.P.H.A., was Director of the Child Welfare Commission of Delaware and the Fargo Child Health Demonstration of the Commonwealth Fund. Dr. Johnson has been director of the Lincoln County Department of Health co-operating with the Mississippi State Board of Health.

DR. G. KOEHLER, member A.P.H.A., for 20 years Assistant Commissioner of Health of Chicago, and for the past year with the Illinois State Department of Public Health, was recently appointed Director of Health and Hygiene in the Springfield, Ill., schools.

DR. JOHN H. GOODNOUGH, of Rock Springs, Wyo., was recently elected President of the Wyoming Association of County Health Officers.

DR. LEMO T. DENNIS, of Rochester, N. Y., has been appointed field worker in child development and parental education of the American Home Economics Association, of Washington, D. C. She succeeds Dr. Esther McGinnis, who returns to her work as associate professor at the Institute of Child Welfare, University of Minnesota.

DR. CHARLES L. TEGTMEIER, of Freeburg, Ill., has been appointed District Health Officer, succeeding his brother, the late Dr. Edward H. Tegtmeier, of Millstadt. Dr. Tegtmeier has practised in Freeburg for 24 years. He served as Mayor of the city for 3 terms, and was village Health Officer for 15 years. He will have charge of state health activities in the Counties of St. Clair, Madison, Monroe, Clinton, Washington, Randolph and Perry.

LAWRENCE G. SYKES, M.D., formerly Medical Director of the Connecticut General Life Insurance Company, has been appointed Medical Director of the Life Extension Institute, the position formerly held by the late Dr. Eugene Lyman Fisk.

#### DEATH

DR. WILLIAM WILLIAMS KEEN, distinguished surgeon of Philadelphia, Pa., since 1889 Professor and Emeritus Professor in the Jefferson Medical College, died on June 7, at the age of 95 years.

#### CONFERENCES

August 11, Fourth Annual (one day) Course of Study in Cancer, Commission on Cancer of the Medical Society of the State of Pennsylvania, Lewistown, Pa.

August 12-18, Los Angeles County Public Health Exposition, Los Angeles, Calif.

September, Ninth Congress of the International Society for the History of Medicine, Bucharest, Rumania.

September 6-9, International Union Against Tuberculosis, The Hague.

September 12-19, American Hospital Association, Detroit, Mich.

September 26-October 1, National Congress of Parents and Teachers National Board of Managers, Chicago, Ill.

October, 1932, Health Committee of the League of Nations, Geneva.

October 3-7, Twenty-first Annual Safety Congress and Exposition, Washington, D. C.

October 22-24, Conference of State Sanitary Engineers, Washington, D. C.

October 24-27, 61st Annual Meeting, American Public Health Association, Washington, D. C.

## Recent Advances in Fumigation of Ships

C. L. WILLIAMS

*Senior Surgeon, U. S. Public Health Service, Rosebank, Staten Island, N. Y.*

THE problem of rat eradication on ships has been intensively studied in this country principally by Creel and Simpson,<sup>1</sup> Grubbs and Holsendorf,<sup>2</sup> Akin and Sherrard,<sup>3</sup> and Williams.<sup>4</sup> During the past 3 years, the whole subject has been under review by a commission of the League of Nations coöperating with the Office Internationale d'Hygiène Publique. As a part of their program, systematic studies of fumigation and directly related procedures were carried out at the New York Quarantine Station. These studies form the basis for the present paper.

From data available at the beginning of this study, it was apparent that: (1) only about 10 per cent of ships were persistently and heavily rat-infested, the other 90 per cent exhibiting variable infestation or complete freedom from rats, and (2) that infestation was largely dependent on the extent and depth of rat harborages, maintenance of large colonies being due principally to breeding on board.

These conclusions pointed the way to two distinct lines for investigation. One pursued by Akin and Sherrard<sup>5</sup> was the possibility of segregating ships according to degree of rat infestation, the other to develop more effective fumigation methods for treatment of infested ships. The latter study has taken much time and physical labor. It has involved an intimate and extended study of the details of ship construction, as well as the development of improved methods of introducing fumigating gases.

The fumigants in general use on ships today are hydrocyanic acid and sulphur dioxide. The modern cyanide fumigants are liquid

HCN and Zyklon. The possibilities of sulphur dioxide have not yet been fully investigated and it will be only incidentally referred to in this paper.

Liquid HCN is packed in heavy steel cylinders, from which, for fumigation purposes, it is sprayed by air pressure. The liquid is the most effective and adaptable form of HCN, but requires the most apparatus. It is also the most dangerous to handle.

Zyklon and Zyklon discoids are liquid HCN absorbed in inert material—kieselguhr and wood fiber discs respectively. It is packed in heavy metal cans and used by spraying on the floor.

#### PENETRATION OF GASES

The first step was to discover, by extensive opening and tearing out of harborages *after* fumigation, the locations wherein rats escaped the gas. A number of specific instances are cited in a recent *Public Health Report*.<sup>5</sup> The net conclusion was that lack of penetration, particularly into dead air spaces, was the principal cause of failure.

Molecular diffusion of gases is a relatively slow process and probably is only a minor factor in the dissemination of fumigant gases. Apparently, this is principally accounted for by convection and by dynamic forces, mainly wind pressure.

When a rat is placed in a small box carefully sealed except for a single  $\frac{1}{4}$ " hole, it will pass through a 2-hour exposure to the standard amount of HCN without apparent effect. If one additional  $\frac{1}{4}$ " hole is made in the box, a similar exposure will kill the rat. The difference is due to the establishment of an air current.

Rat harborages with only one opening are quite common on ships, those usually most difficult to treat being spaces under floors in the holds and burrows into cold storage insulation. In the latter instance, even injection of the fumigant by compressed air often fails to project it to sufficient depths.

#### ABSORPTION

It has been shown that bulk materials, particularly when moist, rapidly absorb both HCN and  $\text{SO}_2$ , but even flat surfaces take up appreciable amounts of gas, the amount increasing as roughness or porosity of the surface increases. The amount of moisture present seems to be most important, though temperature also has a distinct effect.

Absorption influences fumigation by removing gas from the air and thereby reducing the concentration. Within small enclosed spaces where the absorptive surfaces are extensive, in relation to the volume of enclosed air, the gas may never reach a lethal concentration.

In cold storage insulation, the highly porous insulating material absorbs so much gas as to make this a major factor in preventing effective fumigation even by direct injection. In loaded ships, the cargo appears to absorb very considerable amounts of the gas, so much that no allowance in dosage should be made for space occupied by cargo.

#### HCN CONCENTRATION

There being very little data available as to the amount of gas actually in the air of fumigated spaces, one of the first steps was to develop a simple colorimetric method of determining HCN concentrations. A large number of tests has disclosed that the theoretical maximum concentration is rarely reached and that during exposures there occurs a steady reduction of concentration, very largely dependent on atmospheric disturbance as well as absorption.

Inside of rat harborages, concentration was found to vary greatly. In some it would be as high as in the hold; in others it would be zero. Nor was it always possible to predict, even approximately, what would occur. Entirely enclosed spaces, if no cracks presented, were usually impervious, while the presence of many cracks generally admitted plenty of gas. In dead ends gas was usually sub-lethal, under floors sometimes entirely absent.

#### TOXICITY FOR RATS

To appreciate the influence of concentration, it is necessary to know the lethal time relationship. Akin and Sherrard,<sup>3</sup> Barcroft,<sup>8</sup> and the writer have found that 1/8 to 1/5 oz. liquid HCN per 1,000 cu. ft. will kill exposed rats in 30 minutes.

It will be seen from this that in a standard fumigation (2 oz. HCN per 1,000 cu. ft.—exposure 2 hours), the dose represents a theoretical concentration of 10 times, and the exposure one that is 4 times the lethal minimum. While in most cases both the amount and the time are more than required, where deep harborage is present even these margins may be insufficient.

#### RAT HARBORAGES

On ships, rat harborages are of four general types: open, partly enclosed, completely enclosed, and burrows. Nests in the open usually indicate a scarcity or overcrowding of better harborages.

From the viewpoint of the fumigator, harborage is (1) pervious, (2) capable of being opened to insure penetration, and (3) impervious and inaccessible. The last named covers any impervious harborage that cannot be opened without costly damage, or that cannot be reached.

The air jet hydrocyanic acid sprayer

Cold storage and similar insulation was found to present the greatest problem. The insulating material is always a soft substance into which rats burrow long distances. Merely removing portions of the retaining sheathing is of no manner of use; it is essential to open each burrow. In badly infested areas this is tantamount to complete removal of the insulation.

#### DIRECT INJECTION OF FUMIGANTS

Confronted with the knowledge that the fumigating gas failed to penetrate into many harborages and that a large proportion of these could not justifiably be opened except in the presence of reasonable evidence of plague infection, three lines of procedure were considered and, to a greater or less extent, investigated: to increase the amount of gas, to increase the time of exposure, and to inject the fumigant directly into harborages.

Neither increasing the amount of fumigant nor the time of exposure was desirable. Both increased the cost directly; one also increased the time required. Both were bound up with the problem of maintaining concentration. They are still under investigation. It may be stated now, however, that increasing the exposure from 2 to 3 hours produced a distinct increase in the effectiveness of the fumigations.

The third procedure—direct injection of the fumigant—was promising and has been studied at some length. The first projection apparatus used was a converted vacuum cleaner which was fed Zyklon. It was effective but clumsy. The next plan was to force

air through a can of Zyklon and lead it to points of application through a long rubber hose. This method is reasonably effective but has the disadvantage that dosage is inaccurate; at first, the air becomes heavily laden with HCN, but as evaporation proceeds the Zyklon is chilled until finally very little HCN is taken up.

The inaccuracy of the Zyklon method led to the use of liquid HCN, which, while more troublesome and dangerous to handle than Zyklon, is far more adaptable. First efforts were confined to direct spraying within harborages. For this purpose was used a trigger valve controlled sprayer at the end of a supply tube. The apparatus was much improved by replacing the cylinder of liquid with a strong glass bottle which was carried slung from the shoulder. Pressure was supplied in this bottle by screwing down a steel capsule of highly compressed  $\text{CO}_2$  onto a hollow pointed needle, which led into the bottle through a check valve.

#### THE AIR JET SPRAYER

This apparatus, while superior to the Zyklon pump, had the disadvantage that the liquid could not be projected very far, spraying only the immediate vicinity of the nozzle. The next step was to mount air tanks and a compressor on the fumigating boat (similar apparatus may be mounted on a light truck), and to construct an air jet projector. As now in use, this is an oxy-acetylene torch with the liquid HCN, under pressure, attached to the acetylene side and air pressure to the oxygen side, both supplies being controlled by spring valves

Injecting HCN under raised flooring

Rat burrow into cold storage insulation, chalk-marked for direct fumigation. Note loose cork that the rats have pulled out through the opening directly below the cross mark.

operated by a single handle. Experience has shown the best spray is thrown with 100 lb. pressure on each line. A nozzle operated on the atomizer principle throws an equally good spray and can be operated with much less pressure on the liquid line—about 30 lb. In the open, the visible spray is projected about 8 to 10 feet, the invisible vapor much further. This apparatus is an extremely effective fumigating instrument. It, however, has its disadvantages—two of them. One is that it may be too effective, that is, the relatively very large amount of fumigant introduced into a closed space may become a later hazard by failing to dissipate after the fumigation; being inaccessible to the fumigators, they cannot determine the concentration before leaving. The other is that the hose line, full of liquid HCN under high pressure, is a hazard to the fumigator handling the apparatus.

To overcome these disadvantages a return was made to the method of passing air through the fumigant, this time, however, through 18 to 30 lb. of liquid HCN instead of 5 lb. (gross weight) of Zyklon. This has worked well. The lesser surface prevents too rapid evaporation and the greater mass prevents too rapid chilling. Only one hose line goes to the projector, this carrying air laden with HCN vapor, the latter in far smaller amount than is projected by the spray, but quite sufficient for the purpose in hand. Should the line break, the fumigator is sprayed with air, containing HCN vapor it is true, but a very different proposition to a stream of liquid HCN. It is presumed that it is of course realized that when using any of these direct injection apparatuses, the operators wear gas masks.

The air jet sprayer was developed to project the fumigant directly into enclosed spaces. It was at once adapted, however, for general spraying of liquid HCN into holds. In this form it is operated from the deck. The nozzle, being horizontal, shoots the gas toward the sides, while the back pressure causes the nozzle, hanging free at the end of the supply tubes, to fly around in all directions. The result is a thorough distribution, at once, of the gas to all parts of the hold.

#### PRELIMINARY INSPECTION

All fumigation study, but particularly the development of direct injection apparatus, has more and more emphasized that a preliminary inspection of the ship, as the first step after the fumigating crew comes aboard, is an absolute essential of adequate and effective fumigation. While on the majority of vessels there will be found no harborages requiring direct injection, when they do exist they must be located and marked beforehand. It is too difficult to search them out while wearing a gas mask and carrying an injection apparatus.

On most infested ships, there will be some harborages which will protect rats if undisturbed, but which can be readily opened to admit sufficient gas when detected during preliminary inspection.

#### RAT-PROOFING

Rat-proofing requires here some mention, but cannot be entered into at any length. It is, however, inextricably bound up with fumigation.

As has been stated, rats sometimes escape fumigation in one or two deep harborages, remaining as a nucleus from which the colony is rebuilt. When these few harborages are eliminated, subsequent fumigation kills all the rats on board and the persistent colony disappears. Such selective rat-proofing has been extremely useful in many cases.

#### FUMIGATING LOADED SHIPS

In essentials, a loaded vessel presents to the fumigators a ship in which has been placed a relatively enormous, though temporary, rat haborage and one in which the permanent harborage in the holds is covered.

A study of cargoes has shown that they may broadly be divided into package or lump cargo, fine bulk, and bulk liquid. Bulk liquid is in itself dependably rat eradivative and may be passed out of the picture. Finely divided bulk packs into a relatively solid mass, into which gas penetrates but a short distance; fortunately, the same applies to rats. Its worst feature is that it rather completely covers up the permanent harborages.

Package or lump cargo presents numerous interstices into which rats readily penetrate. It has been found, however, that HCN gas will generally reach the rat through any opening through which the rat itself can pass. Dead ends appear to be relatively infrequent, so that the cargo itself is a rather poor protection to rats.

Cargo never fills the holds completely. Always there is a space between it and the deck above, throughout which the gas disseminates. In the case of package or large lump cargo, there are also spaces at the sides and usually along the faces of bulkheads, which permit the flow of gas down the sides as well as over the top, and provide a route for air currents passing through the cargo.

Into the lower levels of loaded holds gas must be introduced by way of the ventilators. When Zyklon is used, the dosage on different levels is inexact. When liquid HCN is used, the delivery tube is guided into each level in turn and exact doses are introduced. Rats under the floors cannot be reached by gas in the holds, but may be

reached through the sounding pipes into the bilges. To date, it has not been thought justifiable to introduce a full dose of HCN via this route, but it is believed possible to accomplish bilge fumigation with a motor-driven blower.

Ventilation of loaded ships has not appeared as a material problem. Accessible portions of holds have been found to clear in about the same time that empty holds will clear, while the inaccessible portions are found clear by the time they are reached in the process of unloading. The exceptions to this general rule have appeared only when the ship's crew closed the hatches *and ventilators* after the departure of the fumigating crew.

To prevent accidents, however, the only reasonable course to pursue after a loaded fumigation is to leave a fumigator as a guard during unloading operations, until he is convinced that gas has disappeared from all parts of the holds. Guards may be kept on rat-infested vessels to collect rats uncovered in and under cargo.

In general, a loaded fumigation carefully performed may be counted on to kill 80 per cent of the rats on a ship. The exceptions that have been noted have appeared mostly on ships in which empty fumigations failed of this degree of effectiveness and on vessels harboring rats under floors in holds.

#### RAT INFESTATION INSPECTION

No dissertation on improved fumigation methods is complete without at least a few words on infestation inspection. The origin of this procedure in this country was undoubtedly the observation that fumigators were able to predict, at least approximately, the rat yield.

Through careful studies of Akin and Sherrard, since amply confirmed,<sup>7</sup> the signs of infestation—rat droppings, rat runs, rat tracks, and cutting or gnawing—have been classified and evaluated, so that today an inspector can determine, with remarkable accuracy, in a relatively short time, the number of rats on a ship, their location and, in some degree, how long they have been present. The procedure has become of tremendous value in eliminating fumigations of ships already free of rats. It is one of the essential bases of the international quarantine agreement now in effect.

#### TEST PAPERS

An extremely useful and practical chemical test for HCN concentration has been developed by Sherrard.<sup>9</sup> It consists of dried strips of filter paper impregnated with mercuric chloride, methyl orange, and glycerine in definite proportions. When one of these is dropped into

a hold, it will turn a distinct pink color, readily discernible from the deck, in the presence of HCN. If the color change is not distinct in 2 minutes, the hold may be safely entered by fumigators. The test is quite as reliable as test animals and simpler in every way to use, with the single restriction that the papers after turning pink tend to bleach, even in the continued presence of HCN, so that additional papers must be used for further tests.

### FUMIGATION RESULTS

Improvement in fumigation methods should be measured by improvement in results. The measures described herein have been developed, tested, and put into use at the New York Quarantine Station during the past 6 years, the essential figures over which period appear below.

	1925	1926	1927	1928	1929	1930	1931
Rats per infested ship.....	18.1	22.1	22.0	21.1	21.8	18.0	15.2
Rat-infested ships—per cent of all ships referred to the Fumigation Division.....	49.1	42.3	30.9	23.0	31.5	24.6	16.0

# Ages of Health Officers in Relation to Professional Training

JOHN A. FERRELL, M.D., DR.P.H., F.A.P.H.A., AND PAULINE A. MEAD

*Rockefeller Foundation, New York, N. Y.*

ALTHOUGH the age of a health officer is important for several reasons, the present discussion will be confined primarily to its influence on his taking university training in public health. The young physician who has been graduated at a grade A medical school within the past 10 years, as a rule is well grounded academically and medically. He is able to meet university admission requirements and to carry successfully its courses in public health. In view of his remaining years of usefulness, his investment of time and money in public health training should yield a real return.

So much cannot be said for older physicians. Those who were graduated a score of years ago, for example, as a rule are not well grounded in the basic sciences and cannot satisfactorily take most of the university courses in public health. Moreover, there would be less incentive for them to invest time and money in courses of training when their expectancy for vigorous health would be for a comparatively brief period. Experience has shown that physicians not over 35 years of age are most satisfactory as students of public health, but exceptional men up to the age of 40 do reasonably well. While occasionally men above this age may carry courses successfully, in general they find the work difficult and at times embarrassing.

The physician who has grown old while serving as a full-time health officer has had opportunity to acquire a great deal of useful knowledge and practical experience, and even though he may be lacking in certain technical subjects, he may play a very useful rôle in administrative and routine health measures. Until schools of public

health were established, training was obtainable only in the school of experience. As will be observed later, only a beginning has been made by health officers in taking professional training in public health.

Table I presents the age distribution of 48 state health officers and 9 provincial health officers. The state health officers have an average age of 56 and the provincial health officers 52. One provincial health officer is 37 years old. With this exception, all of the state and provincial health officers are 40 or over.

Of the 557 full-time county health officers in the United States in January, 1932, the available records did not give the ages of 30. The age distribution of the remaining 527 is given in Table II. In each of 2 states having 2 and 8 health officers respectively, or a total of 10, the average age is 62. In 10 other states there are 183 health officers with an average age of 45 or less. From Table II it will be noted also that in the group under 35 there are 93 county health officers in 20 states, and that in the 35-40 group there are 54, representing 18 states. These two groups, which may be regarded as including the potential students for schools of public health, have a total of 147. Among the county health officers in the states, 30 have had school of public health training—usually 1 year. As of January, 1932, Tennessee reported 5 county health officers who have had school of public health training, and Maryland 5, whereas 13 other states reported only 1 or 2 with such training.

In Canada, there were 32 county health officers in January, 1932. Their age distribution by provinces is shown in Table II. The ages of 29 were available and averaged 40 years. Of these, 18 have had school of public health training. The record of Quebec is conspicuous, in that the average age of 24 of her 25 county health officers is 39 years, and 14 have had training in a school of public health.

In the United States, of the 966 cities having 10,000 or more inhabitants, only 407 have full-time health officers. Of 249 of these for which we have records, the average age is 52 years. Their age distribution will be found in Table III. Of the 158 full-time city health officers whose ages were not available, 150 are non-medical: 32 in Massachusetts, 51 in Pennsylvania, and 27 in New Jersey.

#### SUMMARY

1. The age distribution of 862 full-time state, provincial, city and county health officers is as shown in Table IV.

2. Of the 208 health officers under 41 years of age, 38 have attended schools of public health—a percentage of 18.2.

TABLE IV  
AGES OF 862 FULL-TIME HEALTH OFFICERS

Kind of Health Officer	Under 35	35-40	41-50	Over 50	Total
State			9	39	48
Provincial		1	2	6	9
County ( <i>U. S.</i> )	93	54	152	228	527
County ( <i>Can.</i> )	12	7	5	5	29
City ( <i>U. S.</i> )	19	22	79	129	249
Total	124	84	247	407	862

3. In the age group under 35 there are 124 health officers, of whom only 25 have had university training in public health.

4. University courses should be supplemented by practical field training. As the age group 41-50 is at a decided disadvantage with respect to university courses, practical intensive courses should be offered for them.

5. Although the total number of health officers having diplomas in public health is still quite limited, the number taking the training and planning to take it is showing a yearly increase.

NOTE: The Directory of the American Medical Association was the source of our information as to the ages of health officers, and the *Public Health Reports* were consulted to ascertain the city health officers who are physicians and those who are not.

## Eye Defects in the Savage

IN the recent film called "Trader Horn" there were about 200 savage African tribesmen, especially imported from Africa by Hollywood. A group of eye specialists in California examined the eyes of every one of these men, with this interesting result: that the respective percentages of near-sightedness, far-sightedness, myopia, and other common eye defects were almost the same as the averages for men and women of America. Undoubtedly the abuse of our eyes is the cause of much defect in vision, yet this study of the savages' eyes shows that the human eye has a natural tendency to imperfection.

# Studies on Ringworm Funguses with Reference to Public Health Problems\*

LEE BONAR AND ALICE DOMSLER DREYER

*Department of Botany, University of California, Berkeley, Calif.*

THE type of skin infection commonly known as ringworm has long been a problem met by the physician treating skin diseases. During recent years this has come to be recognized as a matter of real concern for officers responsible for the administration of certain types of public institutions patronized by large numbers of our population. The high incidence of this type of infection has been repeatedly observed and pointed out. During the past 3 years studies have been carried on at the University of California at Berkeley, by Drs. Robert T. Legge and H. J. Templeton, of the Earnest V. Cowell Memorial Hospital, and the writers of the Department of Botany.† Certain aspects of the work have been,<sup>6</sup> or will be reported elsewhere, while the results of laboratory studies on certain phases of the work are herewith given.

The funguses causing this type of infection are found in the epidermis and the hair growing on infected areas of the body. Skin scales and hair are separated from these lesions and bear the hyphae, Figure I, which are viable and capable of starting a new growth of the fungus given favorable conditions.

Such fungus bearing material is especially apt to be dislodged in dressing rooms and in showers. These infectious materials on the floors of rooms used by numbers of individuals form a ready source of infection for the feet of other persons. The high incidence of this type of infection on the feet of persons using such rooms certainly lends very strong evidence to the support of this as a common method of spread.

Is the fungus material so deposited capable of making actual growth on the floor surface and so multiplying the possible source material for infection? These funguses are well known to be keratin

---

\* Read at the Third Annual Meeting of the Western Branch American Public Health Association, at Denver, Colo., June 11, 1932.

† Grateful acknowledgment is made to the Research Board, University of California, and to the Executive Committee of the Associated Students of the University of California, for financial support for this study.

loving organisms growing vigorously on materials such as hair, wool, silk, horn and feathers. Data as to their ability to grow on other types of natural materials are very scarce. An effort has been made to collect evidence as to the possibility of growth on materials such as are to be commonly found on the floors of dressing and shower rooms. Repeated examinations have consistently shown the presence of quantities of hair in any cracks in floors, between boards, under lattice work drain boards, and under mats or in cracks in cement.

Microscopic examination of hair from such situations, where there is sufficient moisture, will often show the presence of fungus growth on and in the hair. This type of fungus growth has not been demonstrated to be that of a dermatophyte, due to the great difficulty of isolating these comparatively slow growing organisms from such material. Material consisting of hair and other debris from the cracks in floors was brought into the laboratory, moistened with distilled water, and sterilized. Pure cultures of a number of species of ringworm funguses were planted on such material, and all yielded growth, showing that such material, when afforded sufficient moisture, will serve as admirable food material for the growth of these funguses.

The question as to whether these dermatophytes are able to make actual growth on wood as do many other funguses has lacked a satisfactory answer. Specimens of new sound wood of different types,

FIGURE I.—Photomicrograph showing mycelium of *Trichophyton interdigitale* imbedded in skin scale

oak, Douglas fir, and pine, were sterilized in flasks after moistening with distilled water, and then inoculated from cultures of a number of species of dermatophytes. These cultures were kept under conditions favorable for possible growth for 6 months' time, but there was no detectable development of fungus in any of the cultures.

Samples of wood were taken from the floor of an outdoor pavilion where the floor boards were somewhat weathered and discolored on the surface due to some years' exposure, but were still apparently sound. These were placed in bottles with distilled water and autoclaved. Blocks of sound new wood were prepared as checks. These were inoculated with fragments from tube cultures of *Trichophyton interdigitale* Priestley, and kept at room temperature. No growth on sound new wood of check. Twelve samples of weathered wood were used. Growth of the fungus developed on three blocks. The growth was very slow in developing and somewhat limited in its extent.

Those failing to show growth were examined by reculturing on agar medium from the inoculum placed on the block, and positive cultures showed that the fungus was viable, but unable to grow except on certain blocks, these apparently affording the food material necessary while others did not. This demonstrated that such old weathered wood may possibly support a growth of this type of fungus.

A point of equal or greater importance to be considered, is whether these funguses may possibly grow on material accumulating on the surface of the floor regardless of the type of floor considered. Surfaces that are subject to frequent wetting tend to accumulate a film or coating of slime. This may in some cases, when not thoroughly cleansed at frequent intervals, show a greenish color due to the growth of algae.

Portions of sound boards, blocks of cement, and bricks that had been thoroughly soaked by continued exposure to wetting for some time, and showed an accumulation of such slime, were taken into the laboratory, placed in culture chambers, and sterilized. The surface was inoculated with a pure culture of *Trichophyton interdigitale*, and they were held at room temperature. A very evident and rapid growth of the fungus resulted (Figs. II and II A). Scrapings of algal growth were made and this material was sterilized and then inoculated with pure cultures. Rapid and abundant growth of the fungus resulted. It is therefore evident that any accumulation of such algal or bacterial slime on the floor or beneath floor mats or drain racks will afford materials for the actual growth and development of this type of fungus, and such growth yields spores readily distributed on any object coming in contact with it. Cracks and fissures in floors would

FIGURE II—Sound wood covered by brown slime, 2 weeks after inoculation with *Trichophyton interdigitale*

FIGURE IIA—Cement block covered with thin greenish slime, 2 weeks after inoculation

often retain sufficient moisture between times of wetting to sustain the growth of the fungus. The cultures shown in Figure II were allowed to dry out in the laboratory and remain dry for 6 months. Subculturing from the surface of these after such drying yielded positive cultures, showing that the fungus may remain viable over rather long periods of ordinary drying. It is, therefore, evident that such growth may remain as a source of dissemination of the fungus over indefinite periods of time.

It appears evident from the data here presented that an important factor in the possible prevention of infection is the elimination of conditions that will permit the possible growth of fungus on floors. Hosing down floors will not be sufficient to remove such material, due to the tenacity with which such materials adhere to the floor. This will be especially true of material under mats and grill work sometimes found on floors and runways. Thorough scrubbing at frequent intervals will be of prime necessity, and possibly the application of disinfectants to the floors.

A series of tests has been made on the action of disinfectants on growths of these funguses in such materials as are found on floors. The materials most likely to serve as food for the growth on floors are: hair, accumulations of slime and algal growth, and skin scales. The

preparations used must be such as to be non-irritating to the feet, and the cost of the materials such as to make application practicable.

Zinc chloride solutions are known to have high fungicidal properties, and are used widely as wood preservatives for the prevention of the growth of wood destroying fungus.<sup>9</sup> Tests on the action of zinc chloride solutions were made as follows: cultures of *Trichophyton interdigitale* were grown on bundles of human hair in culture tubes. When there was vigorous growth on these hair cultures the bundles of hair were laid on blocks of wood that had been placed in large culture dishes and sterilized. Before sterilization the blocks were wet with the zinc chloride solution and enough of the solution provided so that the blocks were about half covered by the solution.

The growing cultures were laid on the surface of the moist blocks, and time allowed for the diffusion of the disinfectant into the hair mat, without immersing it in the solution. This treatment would more nearly approximate the conditions to be met with on a floor surface than would be the case if the growing cultures were simply immersed in the disinfectant solution. Portions of the hair mat were removed at intervals and subcultured for growth of fungus, and results are shown in Table I.

TABLE I

ACTION OF ZINC CHLORIDE SOLUTIONS ON CULTURES GROWING ON HUMAN HAIR

Percent ZnCl <sub>2</sub>	No. of tests	Time of exposure									
		1 hour		1 day		2 days		4 days		7 days	
		Pos.	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.
13.6	3	3	0	3	0	3	0	1	2	0	3
6.8	13	13	0	12	1	11	2	5	8	0	13
5.0	6	6	0	4	2	4	2	4	2		
5.0	5			4	1	3	2	1	4	0	5
2.0	11	11	0	11	0	11	0	10	1	10	1

The killing action was due to the permeation of the hair mats and strands by the zinc chloride. This penetration was checked by removal of the hair mats after killing and repeatedly washing in distilled water. Tests for chlorides gave positive results after repeated washings, showing that there had been extensive penetration of the hair mats.

The results of these tests show a high degree of killing by this agent, in concentrations of 5 per cent or more. The time necessary for killing is rather long, but the high degree of impermeability of the hair, within which much of the fungus material is encased largely accounts for this slow action. It seems that the application of this compound might be advisable to wooden floors, especially in dressing rooms, where the salt would be concentrated in the surface of the wood by evaporation of the water. This residue would then serve to inhibit any fungus growth in organic materials accumulating in cracks in the floor, and apt to become moistened occasionally. Zinc chloride would not seem an advisable disinfectant for the floors of shower rooms, where they are subject to frequent flooding, as it would be washed away before it had time to be effective.

Tests were carried out using some other probable disinfectants, applying them more particularly to accumulations of slime on the surface of wood or blocks of concrete, such as are shown in Figures II and IIA. These slime covered blocks were sterilized in bottles or wide culture dishes, containing small amounts of distilled water, and then inoculated with pure cultures of *Trichophyton interdigitale*. After 2 weeks' time, when a vigorous growth of the fungus had developed on the surface of these blocks, they were transferred aseptically to vessels containing the disinfectant. They were completely immersed in the disinfectant and shaken to insure, as much as possible, thorough contact of the solution with all parts.

After 15 minutes' exposure the blocks were removed to sterile containers and allowed to drain. Subcultures were made at that time in nutrient broth tubes. The blocks were allowed to stand in the containers, and subcultured again after 24 hours. The results of these tests are shown in Table II.

TABLE II

ACTION OF DISINFECTANTS ON FUNGUS GROWING ON THE SURFACE OF SLIME COVERED BLOCKS

Material	Time	1 Per cent Sodium hypochlorite		1 Per cent CuSO <sub>4</sub>	
		Positive	Negative	Positive	Negative
Wood blocks	15 min.	11	3	7	0
Wood blocks	24 hrs.	7	17	7	0
Brick	24 hrs.	0	4		
Concrete	24 hrs.	0	4		

The sodium hypochlorite solution was prepared from standard commercial solutions on the market. The copper sulphate solution was prepared by using the common hydrate  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ .

The results here shown, although for a small number of tests, indicate that sodium hypochlorite solutions must remain in contact with this material for a considerable period of time to be appreciably effective. The copper sulphate solution is entirely ineffective in the concentration, and for the time intervals used. These results strongly indicate that the probabilities of attaining successful disinfection of such surfaces are slight, unless the disinfectant is to remain on the surface for at least a number of hours. The disinfective action will evidently be in inverse ratio to the amount of organic matter on the surface, and this emphasizes the need for a high degree of cleanliness on such floor surfaces.

A series of tests on the action of sodium hypochlorite on dermatophytes imbedded in skin scales was made. Fragments of skin were collected from cases that on culturing yielded a high percentage of positive cultures of *Trichophyton interdigitale* and *Epidermophyton cruris*. These fragments were soaked in a 1 per cent solution for varying periods of time, washed in sterile water, and planted on nutrient agar. The results are shown in Table III.

It is obvious from these results that a high percentage of killing of these fungi is attained only after exposure to the solution for 1 hour or longer. This becomes an important point in connection with the use of such solutions in foot baths. This same sodium hypochlorite solution shows a complete killing action on spore suspensions of these fungi in 5 minutes in dilutions up to 1-5,000. The degree of disinfection attained depends on the readiness with which the solution comes in actual contact with the fungus hyphae. The fungus material imbedded in hairs or in skin scales is encased in material that

TABLE III  
DISINFECTANT ACTION OF 1 PER CENT SODIUM HYPOCHLORITE ON SKIN SCALES  
INFESTED BY DERMATOPHYTES

Organism	Control		Time of exposure					
			10 minutes		30 minutes		60 minutes	
	Plants	Positive	Plants	Positive	Plants	Positive	Plants	Positive
<i>Trichophyton interdigitale</i>	60	33	50	18	50	11	50	3
<i>Epidermophyton cruris</i>	30	14	60	10	10	7	60	0

is very highly impermeable to anything in a watery solution, and this is a fact that must be kept in mind in this work.

Another method of avoiding the possibility of infection from the floor is by the use of bath shoes, to prevent the feet from coming in contact with the floor. Such a procedure is followed in certain institutions, and the evidence to date is such as to lend very strong support to this procedure.<sup>6b</sup> The enforcement of regulations concerning the wearing of shoes in public institutions adds to the troubles of the officers in charge, and may be difficult in some instances, but the wearing of shoes will eliminate to a very high degree the possibility of the bather coming in contact with the infectious material.

Bath shoes are of various types and materials, such as rubber, paper, leather, and wood. Laboratory tests have shown that the dermatophytes are capable of making growth on leather (Figure III) when it is kept moist, although such growth is exceedingly slow, and many tests have yielded negative results.

Attempts to grow fungus on strips from rubber bathing shoes have shown that it was not able to grow on sponge rubber such as is commonly used in bathing shoes, but one series of tests showed growth on the fabric lining from rubber bath shoes (Figure III). These shoes had been used for some time, and the growth of the fungus might possibly be accounted for by the accumulation of organic matter in the fabric, or by materials with which the fabric was impregnated. This idea is advanced, since we have been unable to demonstrate that these funguses are capable of digesting clean cellulose material. Similar tests made on material from old bathing shoes that were made of sponge rubber alone have yielded only negative results.

#### THE DISINFECTION OF CLOTHING IN RELATION TO POSSIBLE PREVENTION OF INFECTION

Due to the nature of this disease it is evident that clothing, towels, and bath mats used by individuals suffering from this type of infection may readily bear skin particles permeated by the living hyphae of these funguses. This has been quite generally accepted as a condition of fact; and where such clothing is subject to common laundering there is a strong likelihood that the infectious material may be generally distributed to the articles so handled. This is the basis for the name commonly applied to this type of infection in one country where it is known as "dhobie itch." The name, dhobie, is that applied to the native laundryman.<sup>1</sup>

It can be readily demonstrated that these funguses are able to make vigorous growth on wool and silk fabrics, when there is sufficient

moisture present, Figure IV. They actually grow in and on the strands of the fabric and digest them, so that eventually there is a breakdown and disappearance of the material of which the fabric was composed. Repeated tests of this type have failed to yield evidence that these fungi are able to attack and digest the cellulose materials of cotton or linen fabrics. Certain statements may be found in the literature<sup>3,4</sup> to the effect that they may grow on cotton, but no definite experimental data are given to support this in any report that has come under our survey. Physiological studies show that they require certain types of complex organic nitrogen compounds as a source of nitrogen for their development, and these substances are entirely lacking in materials made up of cellulose.

It is not likely that there would be sufficient moisture in soiled clothing to support an active growth of these fungi in the fabrics under the conditions commonly met with in handling such clothing, although certain cases have been reported where such seemed to be true. There are, however, rather frequently reported cases of infection of the hands of persons engaged in the handling of soiled clothing, as in local laundries.

Studies have been carried on during the past 2 years on the possible disinfecting action of standard laundry and dry cleaning processes on clothing or fabrics bearing viable fungus material.

FIGURE III—Two on left showing growth on fabric lining of rubber bath shoe; center, no growth on sponge rubber; 2 on right, growth on leather from shoe. Age of culture, 6 weeks

FIGURE IV—No discernible growth on cotton, beyond mass of inoculum

## TEMPERATURE STUDIES

In an attempt to demonstrate the effectiveness of standard laundry methods in incidental disinfection of articles that carry dermatophytes, the temperature factor is obviously paramount. Verujsky<sup>10</sup> reported results on thermal death point studies on spore suspensions of *Trichophyton tonsurans* and *Achorion schoenleinii*. He recorded the first killed after 10 minutes at 49° C., the latter not killed in the same time at 50° C. Weidman<sup>11</sup> reported results of some studies on the temperature necessary to kill a number of the species of dermatophytes in culture, and a brief mention of tests on one species when the material was imbedded in skin fragments.

The funguses used in our tests were: *Trichophyton interdigitale* Priestley, *Trichophyton rosaceum* Sabouraud, *Epidermophyton cruris* Castellani, and *Microsporon lanosum* Sabouraud. These were all grown in pure, bacteria free cultures, and tests were made as follows:

Cultures were grown on agar slants in test tubes until abundant sporulation was obtained. The time necessary for spore formation varies somewhat with different species, but the cultures used varied in age from 15 to 40 days. Spore suspensions were made by introducing into the culture tube a small quantity of sterile distilled water, and then gently working up a spore suspension from the surface of the colony with a soft platinum wire. This spore suspension was then taken off into a sterile tube and agitated to get a homogeneous suspension. Culture tubes were prepared, each containing 10 c.c. of a nutrient solution made up with 1 per cent peptone and 1 per cent glucose.

Five-tenths c.c. of the spore suspension was introduced into each culture tube, and the tubes were then heated for 10 minutes in a water bath which had been brought to the desired temperature. The temperature was read from thermometers held in blank tubes of the same size and containing the same amount of solution. The time interval was reckoned from the time at which the solution within the tube containing the thermometer reached the desired temperature.

At the end of the 10 minutes' exposure the tubes were cooled by immediate immersion in an ice water bath, to insure that the cultures were not exposed to a higher temperature for more than the 10-minute period. Controls were run for each test in tubes inoculated from the same spore suspension and incubated without heating. These cultures were then incubated at room temperature after treatment, and the results read after 14 days. For results see Table IV.

It is a well known fact to students of the dermatophytes that there is a considerable amount of variation in the morphology of these funguses when grown under different cultural conditions. When grown in liquid mediums there is a very considerable development of mycelium without any conidia formation for a period of time. Under certain conditions, especially as the cultures become older, there is a very abundant formation of chlamydospores in the hyphae. Thermal death point studies were made on the four above named species, using

TABLE IV

young colonies of vigorously growing mycelium a few days old, before any spores were formed. Another series was run on material from old cultures in which a large percentage of the hyphal cells were rounded and swollen to form chlamydospores, but where conidia formation had been suppressed. The results of these tests made with several dozens of trials for each species showed that the thermal death point for both the young mycelium, and the chlamydospores was consistently a little below that for the conidia shown in Table IV. Since this was found to be true we are reporting here only the results on that phase requiring the higher temperatures to accomplish complete killing.

*Cultures Growing on Wool*—To each of several 125 c.c. Erlenmeyer flasks 50 c.c. of distilled water was added. To each flask was added 30 small squares (approximately 1 cm. in width) of white Botany flannel. This fabric is a closely woven all wool material. The flasks were sterilized and then inoculated with spore suspensions of the funguses and set aside until profuse growth had taken place, covering all the pieces of the fabric. Microscopic examination showed that the funguses had very completely permeated the fabric, and in some cases the fabric was seen to be digested away to a considerable degree. The squares were then transferred separately to tubes and heated as described above. After heat treatment they were transferred to agar slants and observed for subsequent growth. For results see Table V.

*Cultures Growing on Hair*—Thick bundles of human hair were placed in test tubes with 3–5 c.c. of distilled water, sterilized, and then inoculated with spore suspensions of the funguses. After sufficient growth had developed (2 to 4 weeks,

varying with the species) the entire growth was removed to sterile Petri dishes. The portions of the hair showing abundant growth were selected and separated into small units. These showed abundant growth on and in the hairs when examined under the microscope. Small wisps of infected hair were placed in broth tubes and heated, except for those used as controls. After heating they were cultured on agar slants and observed for further possible growth (see Table V).

*Skin Scales Infested with Fungus Material*—Since it is obvious that clothing and bath room fabrics used by individuals bearing this type of infection will carry skin fragments infested with these funguses, a series of tests were made to determine the temperature necessary to kill them in this condition. Collections of skin scales were made from patients and tested by laboratory culture. Those showing a high percentage of positive cultures from a number of plants were selected for test materials. The scales were cut into small fragments and subjected to heat treatment for 10 minutes in tubes of distilled water, then taken from the tubes and planted in agar plates. The results from these tests are summarized in Table VI.

TABLE VI

THERMAL DEATH POINT OF TWO SPECIES OF FUNGUS IMBEDDED IN SKIN SCALES.  
TIME 10 MINUTES

Organism	Control		Temperature							
			50° C.		55° C.		60° C.		70° C.	
	No. of plants	Positive	No. of plants	Positive	No. of plants	Positive	No. of plants	Positive	No. of plants	Positive
<i>Trichophyton interdigitale</i>	70	50	70	22	40	0	60	0	20	0
<i>Trichophyton rosaceum</i>	20	2	20	2			20	0	20	0

A consideration of the data here listed shows that the dermatophytes are not very highly resistant to heat treatment as applied under moist conditions. The killing temperature is shown to vary somewhat for the different species, *Trichophyton interdigitale* showing the greatest heat resistance, with *Microsporon lanosum* in second place. The effective temperatures here recorded are slightly higher for *Trichophyton interdigitale* than that recorded for complete killing of this species by Weidman,<sup>11</sup> but agree with his findings in that this species is more heat resistant than any other used. Our results and those of Weidman do not agree with the statement of Mitchell,<sup>8</sup> who asserts: "I have been able to culture *Epidermophyton inguinale* from tissue which had been brought to the boiling point in 15 per cent KOH, and obviously ordinary laundering would not kill this organism."

One factor that merits consideration at this point, is the degree of wetting of the material to be treated. In making up spore suspensions one often sees clumping of spores in and about air bubbles in the liquid, and the spores so situated would not be so quickly heated as those more isolated in the liquid. Tests made with *Trichophyton interdigitale* showed that when the spore suspension was shaken with glass beads, decanted, and made up in a more homogeneous suspension, the thermal death point was 5 degrees lower than that shown in our table. Since such a procedure could not be followed in ordinary disinfecting practice it seems better to depend on the figures shown in the table. Practically all laundry treatment of fabrics involves the use of soap, and soap solution serves to lower greatly the surface tension of the bath, and so facilitate complete wetting of all particles.

A number of tests have been made on the possible fungicidal action of soaps. Spore suspensions were made up in 1 per cent soap solutions

(on the basis of dry weight), and allowed to stand for periods of 5, 10, and 15 minutes. Subsequent culturing of these spores on a nutrient medium showed no detectable killing or inhibiting action by the soap. Heating of spore suspensions in such soap solutions showed that the temperature necessary for killing action on *Trichophyton interdigitale* is between 60° C. and 70° C. These tests indicate that there is no appreciable fungicidal action exerted on these funguses by the ordinary soaps that are used in the bath for fabrics, although soaps have been shown to have bactericidal action in such baths, by the work of Elledge and McBride.<sup>2</sup>

#### THE EFFICIENCY OF STERILIZATION OF INFECTED ARTICLES BY STANDARD LAUNDRY ROUTINE

Practically all owners of power laundries in the United States are members of the National Association of Laundry Owners. This body functions to promote the establishment of a standard routine procedure most in keeping with the satisfactory functioning of the business, and this standard routine is more or less adhered to by power laundries throughout the country. By reference to their *Manual*<sup>5</sup> it is found that soiled articles undergo various treatments, which differ primarily according to the fabric, color, weave, and to some extent to the degree to which they are soiled. As the public demands the return of visibly clean and undamaged goods, the laundry finds it necessary to employ the most tempered process that will accomplish this result.

The standard process prescribed for moderately soiled white cotton and linen articles (knitted wear excluded) may be summed up with reference to temperature as follows:

During washing and rinsing such articles are subjected to temperatures of approximately 100° F. (38° C.) for 10 minutes, 120° F. (49° C.) for 5 minutes, and 150° F. (65° C.) for 40 minutes. Soap and soda ash are added to the first two baths. Dirty bundles are subjected to a temperature of approximately 195° F. (90° C.) for 25 minutes. After washing and rinsing the treatment varies with the nature of the article, being either ironed, pressed, or sent to the drying room. Articles ironed or pressed are subjected to a temperature of approximately 320° F. (160° C.) for a short time, while those in the drying room are at 212° F. (100° C.) for approximately 15 minutes.

It is seen from the above that there is little chance of the survival of any of the dermatophytes in view of their heat resistance as shown in the laboratory tests.

Colored cotton articles (except hosiery) are treated as follows:

They are washed for 10 minutes in a bath containing soap and soda ash at 100° F. (38° C.) and this is followed by three 10-minute washings at 120° F.

(49° C.). Rinsing is carried out at this same temperature for about 15 minutes. Following this they are ironed, pressed, or sent to the drying room.

It cannot be stated with certainty, from the viewpoint of the heat resistance of the organisms that this treatment will kill *all* dermatophytes that may be present, although it is obvious that killing would be very nearly complete.

Colored cotton socks, knitted cotton underwear and woollens receive a common type of treatment during the washing process.

The first washing is in soapy water at 100° F. (38° C.) for 25 minutes, and this is followed by three rinsings of 5 minutes each at the same temperature. The subsequent treatment again depends on the nature of the fabrics. Since drying at high temperatures causes shrinkage, these articles are not subjected to such high temperatures, nor are they held in the warm bath for such long periods of time as are common cotton articles.

There is no standard procedure for silks, because of the great variation of articles received. Nevertheless, the washing and rinsing temperatures never exceed 100° F. (38° C.), and excessive temperatures for drying or ironing processes are avoided. Silk mixtures and artificial silks are treated as is pure silk.

From the above account it can readily be seen that the killing of the dermatophytes in colored cotton socks, wool, and silk articles is extremely doubtful. It is on such articles, moreover, with the exception of towels, that the occurrence of the infected material is most frequent, because of the nature of the disease.

#### THE EFFECT OF DRY CLEANING SOLVENTS ON DERMATOPHYTES

Certain types of clothing that are not laundered are subjected to "dry cleaning." Such articles from individuals infected by these fungi may carry infectious material, and recommendations have been made<sup>7</sup> that soaking these articles in dry cleaning solvents would serve to clear them of the infectious material. Such treatment has been recommended for woollen socks to prevent reinfection of cases under treatment. The substances more commonly used for dry cleaning solvents are hydrocarbons, such as gasoline, kerosene, and benzene. Carbon tetrachloride is a component of certain cleaning mixtures.

A series of tests has been made to determine the action of these solvents on four species of dermatophytes. Cultures of the fungi were grown in flasks on fragments of wool fabric and on hair until the mycelium had thoroughly permeated the material. The materials bearing these were removed to dry sterile filter flasks and dried in a 32° C. incubator for 5 days, until they were quite dry. They were then flooded with an excess of the cleaning solvent, and agitated to

insure a complete wetting of the surface of the fibers and hyphae of the funguses by the cleaning agent. The agent used in these tests was Cleaners' "naphtha." After the desired time exposure the fluid was poured off and the wool and hair materials completely dried by passing through the flasks a current of air that had been filtered free of micro-organisms. The particles were then removed to culture tubes containing a nutrient medium, and observed for subsequent growth, and their identity was checked. The results of these tests are shown in Table VII.

TABLE VII  
RESULTS OF THE EXPOSURE OF GROWING CULTURES TO "NAPHTHA" AND  
SUBSEQUENT RECULTURING  
CULTURES GROWING ON HAIR

Time in solvent	<i>T. interdigitale</i>		<i>M. lanosum</i>		<i>E. cruris</i>		<i>T. rosaceum</i>	
	No. of tests	Positive	No. of tests	Positive	No. of tests	Positive	No. of tests	Positive
15 min.	54	54	30	30	30	15	30	30
30 min.	29	29	30	30	30	3	30	30
60 min.	30	30	30	30	60	7	30	10
control	3	3	3	3	4	4	3	3

CULTURES GROWING ON WOOL

15 min.	30	30	30	30	25	25	30	30
30 min.	30	14	30	28	20	14	30	10
60 min.	30	21	30	10	18	3	30	9
control	4	4	3	3	4	4	4	4

It is seen from Table VII that there is very little killing action in these species under 1 hour of exposure, and in no case is it complete in 1 hour's time. The percentage of killing is higher with *Epidermophyton cruris* than with the other three species; this species also gives less vigorous growth on hair than the others used.

Tests of the action of naphtha, kerosene, and carbon tetrachloride on spore suspensions showed no appreciable killing action after 5, 10, or 15 minute exposures.

Tests of the possible killing action of some dry cleaning solvents on mycelium of these funguses imbedded in skin scales were made. It is in the skin scales that the fungus material lodged in clothing will

almost always be found. The action of the solvents on such scales will serve to give us a rather accurate measure of their disinfectant action.

TABLE VIII  
RESULTS OF SOAKING SKIN SCALES BEARING *Trichophyton Interdigitale*  
IN SOLVENTS AND SUBSEQUENT CULTURING

Solvent	Control		Time of exposure							
			30 min.		60 min.		90 min.		120 min.	
	No. of plants	Positive	No. of plants	Positive	No. of plants	Positive	No. of plants	Positive	No. of plants	Positive
Naphtha	20	7	20	3	20	4			20	4
Kerosene	30	12					20	8		
Carbon tetrachloride	20	7	20	7	20	4			20	5

The results recorded very clearly demonstrate that there is at best a very light disinfectant action by dry cleaning solvents on the ringworm fungi that may be borne on the clothing treated.

There is considerable variation in the procedure followed in the handling of articles to be dry cleaned, depending on the nature of the garment, the degree to which it is soiled, and the equipment of the cleaning establishment. In the better equipped standard establishments the treatment for a great many routine articles is immersion and agitation in the solvent for from 1 to 1¼ hours. Where the articles are immersed they must be subsequently dried, and there may be a very appreciable sterilizing action from the drying process, although the temperature is kept in all cases well below 100° C.

#### SUMMARY

1. Attempts to grow fungus on sound clean wood have yielded only negative results.
2. Fungus may grow readily on floor material that is covered by a coating of slime or algal growth.
3. Results of the application of certain disinfectants to growth on slime covered blocks of floor materials are given.
4. The complete killing of *Trichophyton interdigitale* borne in skin scales, by 1 per cent sodium hypochlorite solution requires a time period of 1 hour or longer.

5. Thermal death point studies on spore suspensions, cultures grown in fabrics, and on material imbedded in skin scales show complete killing of the fungus in 10 minutes' time at 75° C., or lower in some cases.

6. The efficiency of the fungicidal action of standard power laundry practice is shown to vary with the nature of the fabric handled and with the temperature applied to the different materials. The standard practice for white cotton fabrics shows a good margin of safety, while that employed for woollens and colored fabrics is doubtful.

7. The application of standard "dry cleaning" solvents to these funguses, either growing in fabric, or imbedded in skin scales, is shown to have a negligible killing action, in exposures of 1 to 2 hours.

## Bulgarian Parents and Teachers Organize

THE International Federation of Home and School announces the organization of the National Union of Parents and Teachers of Bulgaria, which plans the publication of pamphlets of information and the organization of lectures on the principles and methods of the home and school movement.

# Health — Where Can It Be Taught?\*

CLAIR E. TURNER, DR.P.H., F.A.P.H.A. (*Life Member*)  
*Professor of Biology and Public Health, Massachusetts Institute of  
Technology, Cambridge, Mass.*

THE writer's chief qualification for preparing this paper, dealing with a subject involving such diversity of opinion and practice as health teaching in the senior high school, is perhaps that he has no ideal course or perfect program to suggest. For more than 10 years we have been experimenting in the development of health education methods in the City of Malden, but we began with the lower grades completing a program for each successive grade upon the basis of the pupil's previous training. The result is, that we have only within the last year begun the study of the senior high school.

Certainly it is a sound principle for the public school to begin its health training in the lowest grade and develop health behavior as rapidly as possible, gradually increasing individual responsibility as the child becomes older and supplying him from grade to grade with the supporting facts which make health behavior reasonable and which will enable him as an adult to determine sound health procedures when confronted with new situations.

It is unscientific, even if not uncommon, to consider the high school program without reference to what has been done in the lower grades. Communities which have not established a good health education program in the lower grades may need a temporary high school program based upon the need of the present generation of high school pupils. Such a program should be regarded as temporary, however, and should be changed with the changing needs of the pupils. It would be absurd to build a health education program by deciding first what instruction would be interesting to present in the senior high school and pass out those things which are left to the lower grades.

It is easier to form right habits in the first place than to replace bad habits with good ones. Moreover, only a small percentage of children reach senior high school. Both of these facts point to the obvious desirability of carrying each child as far as possible in health training in each grade. We must build the high school program as

---

\* Read at a Joint Session of the Public Health Education and Public Health Nursing Sections of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 14, 1931.

a protecting roof of knowledge and further individual adjustment upon the best structure we have been able to develop up to that time.

We will do well to consider some of the other principles of health instruction which apply both to high school and lower levels.

1. We must recognize the importance of a fresh approach in succeeding years of instruction. In health education we are training children—not merely presenting information. The fact that a habit is once established does not warrant the assumption that no further attention needs to be given to that item of behavior for the remainder of the school life of the child. It may be more difficult to maintain health practices at a higher grade level than it was to establish them at an earlier age. In any training program an appreciable amount of repetition is necessary. This makes obvious the necessity for some new material and a fresh approach in each succeeding year.

The program which we have developed experimentally in Malden may be used to illustrate what we mean by keeping a fresh approach. In the first 2 grades the program is one of informal health habit training without the attempt to present information as such. In the third grade a health reader is used as a guide to the health training program and the pupil is held responsible for a small amount of health knowledge. In the fourth grade the pupil has his first textbook which emphasizes the “how” of health training, with an appreciable increase in the number of health habits or details of behavior considered. In the fifth grade the pupil continues health training with the study of the “why” of health practices considered in terms of illustration and analogy from his own field of experience. In the sixth grade the new approach to health is through the consideration of the biological approach to cleanliness as it concerns the individual and the home.

Definite health instruction is maintained throughout the junior high school with its departmentalized program. This is practical and logical. The child demands further information to support the continued program of health training and a large number of these children will have no opportunity for schooling beyond the junior high school. In grade 7 the pupil goes forward from his recent study of cleanliness in the home to a consideration of the elements and principles of community health, both rural and urban. It is not difficult to associate instruction in personal habits with this subject, and this study, properly related to the work in civics, helps to build a citizen who will support suitable public health activities in his community. In grade 8 the pupil studies elementary physiology based upon a simple knowledge of structure and function and is given as

much information as is practicable for the individual who is without a knowledge of physics, chemistry, and general biology. In grade 9 a study of home nursing and child care is required of all girls. We are considering the possibility of developing instruction in food values and in first aid for the boys.

This summary shows not only the care which has been taken to secure a fresh approach, but also the kind of health background possessed by an increasing number of high school pupils as one city and county after another establish their own well-organized education programs in the lower grades. A course in senior high school in which subject matter and methods are mere repetition will be flat, stale, and unprofitable. There is serious danger of pitching health instruction in high school at too low an intellectual level.

2. We recognize that, although there are certain minimum general standards of health behavior, there is no single set of health rules which is satisfactory to all individuals. In the lower grades we are largely concerned with bringing the child up to some of these minimum standards. In the upper grades we should be increasingly concerned with showing him the difference between health rules and individual needs, in order that his lack of understanding may not develop a disgust for all general principles of health, and that he may study his own physical limitations and learn to live within them. The high school encourages rational action based upon principles rather than on propaganda.

3. We recognize also that health is taught not in the hygiene class alone but through *all* the experiences of the child. The pupil's 10 minutes with the school physician, for example, may contribute the most important piece of health instruction for the year. With this fact in mind, we recognize that the maintenance and conduct of school activities and the health material presented through other subjects of instruction are vital elements in teaching health.

Perhaps you are saying that most of the time has been spent in discussing everything but the senior high school program. When a jig-saw puzzle is put together except for one piece, the shape of the latter is perhaps better understood than as though it were described separately with reference to the other elements which make up the picture.

Our considerations lead us to the inevitable conclusion that health is taught in the senior high school in 3 ways: (I) Through the experiences of the pupil outside of class instruction, (II) Through health instruction correlated with some other subjects, and (III) Through direct instruction in hygiene courses.

I. In every high school the extra-instruction experiences of the pupils inevitably influence their present and future behavior in the right or in the wrong direction. There is neither time nor necessity for discussing in detail the school's responsibilities in this field. They include:

(a) Maintenance in school of those standards of sanitation which we teach as desirable. How often the failure to provide suitable handwashing facilities, sanitary conditions in toilet rooms, the sanitary distribution of drinking water, or the maintenance of satisfactory cleanliness convinces the pupil that the school does not really believe the things which it teaches!

(b) The provision of a medical, nursing, and dental service which approaches its task with a human consideration of the individual, with sufficient time allowance to function efficiently, and the purpose of demonstrating the constructive place of medical science in the life of the individual—rather than a hurried, mechanical, impersonal piece of scientific machinery which considers communicable disease and physical defects with little thought for the personality of the pupil or the attitude toward medical science which is being formed.

(c) The hygienic arrangement of the program, and the best possible coöperation with the home to make the pupil's school day hygienic. Here we have problems involving the length of the school day; the provision of suitable food, relaxation, and recreation; limitation of the pupil load and of extra-school activities; and the development of proper mental, social and emotional health among pupils through a type of school management which will provide right experiences.

II. The teaching of health through correlation is fundamental and important. It shows the pupil that health is a part of life, that healthful living is not a fad of the doctor or of the hygiene teacher but something which has the support of all intelligent people.

The activity program in physical education provides an unusual opportunity to contribute to the maintenance and further improvement of health behavior, constructively, indirectly, and without preaching. It is most important that a clear and coöperative understanding should be developed between the physical education program on the one hand, and health education with its ramifications into all activities of the school health program on the other.

The natural sciences, especially biology, and the social sciences, especially history, have unusual opportunity to provide instruction which will explain and support health principles and extend the appreciation of health values. Most subjects of instruction in the

senior high school can make some contribution to health, and in every course due consideration should be given to mental and physical health in developing the schedules and methods of instruction.

III. What should be done in direct health instruction? We believe that the answer to this question will be found in study and experimentation. Valuable studies and suggestions regarding the high school health program have been made.<sup>1, 2</sup> Doubtless many schools are now experimenting in direct health instruction. From extensive, honest, scientific investigation we shall get the best answers. The problems and the courses needed are not the same for all communities.

Various types of courses have been offered in the past. Some schools have given a course in health or hygiene in each year of the senior high school. We doubt the feasibility of this for pupils who have been exposed to a thorough health education program in the lower grades.

Some schools have provided elective courses for girls, touching the field of personal and social hygiene, under the direction of a teacher or nurse with the proper science and social background and with distinct and recognized ability. Under the direction of the right type of individual these courses have been very successful. The need of instruction in social and sex hygiene at the high school age level presents an important, difficult, and delicate problem, although the approach to such instruction is undoubtedly easier than it was a few decades ago. The apparently successful experiences of Dr. J. R. Earp in teaching social hygiene to mixed groups of college age is interesting, in this connection.\* Probably the time has not yet arrived to teach social hygiene in the high schools under that name or to teach it at all except at the election of pupils in separate groups of girls or boys. Much can be done in the presentation of scientific facts and in the development of right attitudes without any direct reference to sex hygiene.

It seems likely that our first experiment in direct health instruction in senior high school in Malden may be with a problem course for seniors who are not going to college. It will deal with those problems soon to be faced by the individuals as workers, citizens, and parents. Such a course, we feel, should relate to local and personal problems and be conducted in a sense after the seminar method, with the selection of specific problems to which pupils will bring the answer for consideration and discussion. It may be that we shall find that this

---

\* Forthcoming article to appear in the report of the Denver, 1931, meetings of the Health Section of the World Federation of Education Associations. Address Miss Sally Lucas Jean, Secretary, 200 Fifth Avenue, New York City.

is not a sound or practicable answer to the need for some direct health instruction.

In summary then, we must recognize that health instruction in the senior high school must depend in large measure upon what has gone before, that whatever is presented must be largely new in material or approach, or both, and that the health teaching which is possible through pupil experiences outside of class instruction and through correlation may be more important than that which comes through direct instruction. This makes it clear that health education in the senior high school is in a large degree an administrative problem and this in turn suggests the importance of a health committee or a health counselor to assist the principal in meeting his responsibility for the development of an ideal health program.

## Welfare Measures for Employed Boys and Girls, Czechoslovakia

A NATIONAL council for the protection of working boys and girls has recently been organized by the Ministry of Social Welfare of Czechoslovakia. This council consists of 18 representatives of young workers' organizations and is functioning under the chairmanship of the chief factory inspector. It is coöperating with 26 local councils, the organization of which is similar to that of the national council; the chairmen of the local councils are the district factory inspectors. In making the appointments to the councils, the minister of social welfare gives preference to persons with experience in social welfare work.

These councils are working on various questions arising out of the employment of boys and girls; jointly with the factory inspectors they enforce the labor laws as applied to boys and girls; they take part in the work of the public agencies for vocational guidance, vocational training, and protection of apprentices, and engage in general welfare work for boys and girls.—*Lehrlingsschutz, Jugend und Berufsfürsorge*, Vienna, May, 1932.

# Medical Participation in Public Health Work

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A. (*Life Member*)

*Commissioner of Health, Detroit, Mich.*

SOME activities now included in the program of most health departments can be transferred gradually to the general practitioner of medicine. In the interest of child health, in so far as practical, the family physician should become a practitioner of preventive as well as curative medicine. He should take an interest in seeing that his clients are protected against smallpox, typhoid fever, and diphtheria, and that adequate periodic physical examinations are made. The public health service should stimulate interest in extending postgraduate instruction to the general practitioner of medicine to interest him in this type of service, and also to establish reasonably uniform methods of procedure.”<sup>1</sup>

“The health department inaugurated in Detroit, in 1928, a program of participation by the general medical practitioner in official public health procedure, the ultimate objective of which was to secure the sympathetic and whole hearted support of the medical profession in order that the general practitioner might not only practice curative medicine but actively take his part and share his responsibility in the preventive medical program. A campaign to secure protection against diphtheria, for young children, more especially the preschool child, was used to interest and stimulate response from the general practitioner.”<sup>2</sup>

## ESSENTIALS OF PROGRAM

The essentials of a program may be briefly enumerated as: (1) actual medical participation; (2) preparation of the medical profession; and (3) preparation of the public.

Success depends upon a complete understanding between the local public health organization and the medical profession (as expressed through the department of health and the county medical society). Few, if any, medical societies are organized with suitable personnel or finances to carry through a program without the assistance of the health department organization. The two major parties

to the enterprise are: first, the public as represented through local government and specifically the health department; and second, the medical profession as represented through its organized society. While health councils may be desirable in certain communities, they are not essential if the health authorities and medical society will take the initiative, assume the lead, and coöpt such other agencies as have special interest in parts of the program—as for example, the tuberculosis society and other community health organizations and lay representation through such organization as the local chamber of commerce. In the dental field the local dental organization must participate. The medical society can best serve through a public health committee whose action should be reviewed by the council of the society. Every step should be worked out with the sympathetic support of the medical society and all new developments should be submitted to the society for its approval prior to final adoption by the health department.

*Preparation of the Medical Profession*—This involves: (1) a complete understanding by the membership of the local medical society and of district societies, if there be such; (2) the establishment of postgraduate medical conferences; (3) the employment of medical coördinators; (4) undergraduate instruction.

There must be continuous contact between the health department and the public health committee of the medical society, with regular meetings at least bi-weekly. Every opportunity should be available to present the program at the general meetings of the society and at the meetings of the district societies. Special meetings of the participating or coöperating physicians have been found desirable.

Postgraduate medical conferences in communicable disease control for the recognition of early cases of tuberculosis and for the discussion of periodic health examinations should be instituted. These should be designed to attract the physician interested in therapeutics but afford a splendid opportunity to instruct the physician concerning the newer methods of disease prevention. Such conferences have been held in Detroit during the past 3 years and at 10 conferences on communicable disease control there was an average attendance of 235 physicians and, all told, one-third of the membership of the medical society attended some of the lectures. This has created a sympathetic profession, and has not only served as a forum of instruction in modern preventive medicine, but has had the added effect of making better diagnosticians of the physicians and assisted in making more widespread, current knowledge concerning the treatment of communicable diseases. The medical conferences have been built around

the personnel of the communicable disease hospital, whose clinical facilities and staff have been drawn on freely.

There are, unfortunately, certain physicians who never or seldom attend medical meetings of any character and continue to practise medicine of the vintage of the days of their medical school. The employment of medical coördinators to visit such physicians in their own offices has assisted materially in preparing physicians.

In communities which support a local medical school, instruction should be given to the senior class both in the administrative mechanics of the program and in clinical demonstration of the treatment and control of communicable diseases.

*Preparation of the Public*—In addition to the preparation of the medical profession, the health department must actively pursue a program of popular health instruction directed (1) to the public as a whole, and (2) to the individual.

To secure maximum accomplishment in the actual practice of preventive medicine involves three-cornered coöperation of the public, the medical profession, and the department of health. All the known means of general health education should be employed, including such tools as the radio, newspaper stories, newspaper advertising, bill-board and street-car placards, talks to professional, business, social, and lay groups, and the generous distribution of educational material.

Individual education depends primarily upon home visitation by public health nurses (or other educators). Such system of visitation has been found extremely profitable in increasing the per cent of immunization of young children against diphtheria and has served to stimulate parental interest and responsibility. A personal letter addressed to the parent when the child attains the age of 6 months, followed within 10 days or 2 weeks by a home visit by a public health nurse, has materially increased the number of children under 1 year of age who visit the office of the participating physician and secure protection against diphtheria.

#### DIRECT OBJECTIVES

While the principal purpose of the program is medical participation, and instruction of the public to look toward the family physician for preventive as well as curative medical service, the direct objectives may briefly be summarized as (1) the protection of a high percentage of children between 6 months and 10 years of age against diphtheria, (2) vaccination for smallpox, (3) periodic health examination, and (4) periodic dental examination.

*Diphtheria Prevention*—Any health department which does not

organize itself to make available through the office of the family physician the facilities now recognized as available to the modern health department is missing its opportunity.

In Detroit, 1,100 physicians have become actively interested in preventive medicine. No free clinics exist for diphtheria immunization. In the fall of 1929, a communication sent jointly by the medical society and the health department was addressed to every physician, inquiring whether he would coöperate in the campaign by setting aside definite hours during which he would receive at his office, children in need of protection. It was agreed that the physician would charge \$1.00 for each dose of toxin-antitoxin or toxoid in those cases in which, in his judgment, the patients were able to pay for the service. The charge for the Schick test and the reading of the results would likewise be \$1.00, making a total of \$4.00 for the service.

There was nothing in this plan that would prevent the physician from charging his usual office fee if the patient appeared at any hour other than that specified in the agreement. It was further agreed that when, in the physician's judgment, the parent was unable or unwilling to pay for the service, the health department would reimburse the physician at the rate of \$.50 for each treatment and \$1.00 for the Schick test, or \$2.50 for the complete service to each child.

Under such agreement a list of coöperating physicians was established and the city was divided into 35 districts and a card was prepared for each district, listing the name and office address of each physician and designating the hours at which he would receive children for immunization. These lists were used for the convenience of contacting patient and physician and, more especially, by the public health nurses, who later canvassed the entire city.

The result has been that approximately 70 per cent of the preschool children and 80 per cent of the school children have received protective treatments without the use of free clinics. During the past 3 years this procedure has become accepted by the public and physicians, and is automatically bringing about the protection of a high percentage of the child population with a corresponding reduction in the diphtheria death rate.

The program of diphtheria protection has so awakened the interest of the physician in preventive service that during the past 3 years the percentage of preschool children protected against smallpox has increased from 22 to 43. It is obvious that protection against smallpox can be secured in the same manner as protection against diphtheria without the use of free clinics.

The next logical step in the program of medical participation is to secure a periodic health examination for individuals at all ages (from the infant to the adult). Of particular significance to the health department is the effort to find the minimal (or childhood type) case of tuberculosis. During the past year there has been built up in Detroit a group of 400 coöperating physicians who are interested in diagnosing early tuberculosis in children. The tuberculin test followed where indicated by a physical examination and X-ray study has been available at the office of the coöperating physician.

The same general procedure and educational program as described for diphtheria has been followed with the single exception that the health department had no funds with which to reimburse the physicians for non-pay patients. There is being instituted a system of reporting periodic health examinations and vaccinations for which report the health department is paying the physician \$.10 as a contribution against the bookkeeping costs. The county medical society has assumed the responsibility of making the periodic health examinations in schools.

A committee of the District Dental Society has placed in operation a service which involves (1) dental inspection of school children, (2) service for indigent adults, (3) part-pay service for semi-indigent children, and (4) regular pay service for children financially able to meet the usual fee. A list of coöperating dentists has been established and the health department participates in the educational program and in financing the mechanics of the program.

#### ADVANTAGES OF THE PROGRAM

*To the Medical Profession*—Advantages may be briefly summarized as (1) the elimination of free clinics; (2) increase in medical care to the 98 per cent of the population which is supposedly in good health and in normal times employed and better able to pay, which should result in decreasing service to the 2 per cent of the population which is ill at a given time; (3) joint direction and supervision of the program by the medical profession and the department of health; (4) maintenance of professional relationship between physician and patient; and (5) payment to physician at a reasonable rate for service rendered.

*To the Public*—Advantages to the public are briefly (1) a reduction in needless sickness; (2) a reduction in the cost of medical care through the prevention of disease; (3) the assurance of obtaining good medical care in connection with preventive services; (4) distribution of cost, so that those financially able make complete payment

while the load for the indigent is spread on the public tax roll; (5) the stimulation of parental interest and responsibility in disease prevention and the maintenance of personal health.

*To the Health Department*—The advantages to the health department are briefly (1) a reduction in morbidity and death rates, and (2) a conservation of public funds. Since, with the elimination of preventable diseases, the limited health department funds can be used advantageously elsewhere.

#### DISADVANTAGES

From the general viewpoint of medical care, the principal disadvantage of the Detroit plan is that it has been applied only to preventive medicine.

Basically, the plan involves two principles: (1) organized service, and (2) group payment for certain parts of the population. These same principles are fundamental to a program of curative medicine. The details of their application will not be discussed at this time but suffice it to say that their application does not mean any system of state medicine such as has been created abroad. It does involve group purchase of medical service through taxation for the lower wage earning classes. Organized medicine involves practice with available hospital, clinic, laboratory, X-ray, and research facilities. Such facilities already exist in most urban communities with varying plans of application. In rural districts a method of group purchase by taxation will readily provide an organized medical service which can be made attractive to the physician and beneficial to the public.

Several observers have also indicated that they object to the cost of the procedure in so far as diphtheria protection is concerned. It is recognized that the initial cost is high because the number of children in need of service is relatively high. Each succeeding year reduces the cost. Under no circumstances should the cost be charged solely to diphtheria protection but rather to a program of medical participation which will bring increasing dividends. However, in the Detroit experience in no year has the preventive service including payment to physicians exceeded the cost of hospitalization of the 50 per cent of reported cases of diphtheria hospitalized by the Department of Health. Therefore, the city, through its health department, is saving money.

Another disadvantage which should be mentioned is the difficulty of directing such a program. The medical profession by intuition and by training may not be prepared for such an undertaking but only time and mutual understanding between the medical society and the department of health can overcome such obstacle.

One other real difficulty is the time factor. It is granted that free clinics will receive more prompt response from the public but it has been demonstrated that in the course of 3 years one city has been able to bring about the protection against diphtheria of as high a percentage of its susceptible population as has any other city of equal size through the agency of free clinics.

None of the disadvantages are insurmountable. They are heavily out-balanced by the advantages.

## Safety Congress

THE Twentieth Annual Safety Congress and Exposition will be held in Chicago, October 12-16, 1932. The various sectional sessions will include Automotive, Cement, Chemical, Child Education, Community Safety, Construction, Delivery, Taxicab and Bus, Electric Railway, Fire Prevention, Food, Foremen's Forum, Home Safety, Industrial Health, Industrial Nursing, Laundry and Dry Cleaners, Marine, Metals, Mining, Packers and Tanners, Paper and Pulp, Petroleum, Power Press, Public Utilities, Quarry, Refrigeration, Rubber, Textile, and Woodworking and Lumber Manufacturing, and several sessions on Traffic.

## EDITORIAL SECTION

*Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.*

## DO NOT LET UP IN HEALTH WORK OR FUNDS FOR HEALTH WORK

EARLY in his administration, the President of our Association sent out a letter calling attention to the dangers of the depression in regard to public health work, and urging that funds for such work should not be cut down. Instead of getting better, as some of our political optimists have prophesied so many times, the depression has grown worse and from practically every part of the country we get reports of depletion of funds for health work and the discharge of those engaged in it.

It, therefore, seems wise once more to call attention to the dangers of such a course. We are compelled to admit freely that, so far, the health of the people has not been affected as seriously as was anticipated, since 1931 was one of the healthiest years on record. This fact does not, however, satisfy public health people that damage is not being done, especially to children, and there is little question that this will be evident as time goes on whether things change for the better quickly or not. It is a source of satisfaction to us that our affairs are in such good order from the standpoint of health and health organization that we have been able to stand what we have been through without perceptible bad effects, at least as far as nutrition goes.

Other studies, however, have been made that show unmistakably the effects of the financial depression. One of the most interesting of these has to do with the mental health of the nation. More than 100 of the 173 state hospitals have been investigated by means of a questionnaire. While some of these show an increase in new admissions and re-admissions running as high as 20 to 35 per cent respectively, which are traced in part to the depression, when they are carefully analyzed and all factors taken into consideration, those who specialize in this branch admit that there is no rising tide of admission which can be ascribed to the prevailing economic conditions. Psychiatrists are convinced that they are seeing the results of an accumulation of strains rather than the effects of one particular factor. There is, however, a very marked change, directly traceable to the depression, in paroles and discharges. In every part of the country hospitals for mental diseases are having great difficulty in paroling and discharging patients who are well enough to leave. Work is hard to obtain. The families of the patients are in bad condition financially; so they object to receiving mental incompetents back again. It is stated by the Association Secretary of the National Committee for Mental Hygiene that paroles and discharges have diminished from 5 to as much as 20 per cent, in spite of the fact that some superintendents are making every effort to discharge patients when they are fit to go out.

Another result which probably shows the influence of several factors is shown in the birth rate, which is the lowest since the registration area was established in 1915. The 1930 rate was 19.8, while that for 1931 was 17.8 per 1,000 population. It hardly seems doubtful that the depression has had something to do with this. At the same time, the infant mortality rate has been very low, 61.7 per 1,000 live births.

Another feature which is good, as far as deaths and disability go, but is sinister in its origin, relates to occupational fatalities, which have declined 12 per cent from the figures of 1931. Every principal cause of accidental injuries has shown a marked decline, except automobile accidents, which increased 21 per cent. The fact back of this decline which would otherwise be welcome, is unemployment, there being at least 7 million unemployed in this country at present, while some estimates are much higher. By the same token, unemployment has added greatly to the worries, as well as the work of health departments, so that no comfort can be derived from the decrease in industrial accidents. There can be no doubt that there is much evidence of nervous and mental maladjustment, due to the depression, occur-

ring particularly among those who have been hardest hit, the unemployed and their families. Our suicide rate has risen markedly, showing the highest figure on record, except for one year just after the World War.

It is perhaps unfortunate that the statements here made will be read principally by those who already understand the situation and are working with us for a common object, the protection of our budgets for health work. We can only urge that every opportunity be taken to point out the facts to the proper authorities and to work personally, as well as otherwise, against cutting of budgets for health work. The Congress has adjourned without passing the emergency relief bill continuing and extending the help which was given for the drought area in 1931. In one state, alone, some 40-odd health workers have been left without employment. Their work which was calculated to produce permanent value has been discontinued. There is no question that a similar situation is more or less general, inquiry revealing that among more than 200 health departments there has been an average reduction in budgets of 7.4 per cent, some running as high as 43 per cent. Large cities have suffered most but counties and states have also been hard hit.

### A NEW JOURNAL

THIS *Quarterly Bulletin* has been brought into existence in order to make the material emanating from the Health Organisation of the League of Nations more generally available. It is not, however, an official organ and the Health Organisation does not assume responsibility for the opinions expressed in it, except when so stated.

The first volume is full of interesting material, beginning with the Resolutions of the Conference on Immunisation Against Diphtheria. Next there is an excellent report on Medical Education in England by Sir George Newman, and after that a report on the "Milk Supply of North-American Cities" by Professor R. Burri, Director of the Swiss Federal Institute for Milk Industry and Bacteriology. "Tropical Pneumonia" occupies 40 pages, followed by an excellent bibliography.

Perhaps the most interesting chapter is "A Second Analytical Review of Reports from Pasteur Institutes" on the Results of Anti-Rabies Treatment, by Lieut.-Col. A. G. McKendrick. Space permits only a brief summary. This second report which deals with the year 1929, covers 69,709 treatments which he compares point by point with 31,656 previously given.

Of those treated with killed vaccines, 0.80 per cent developed rabies, live vaccines 0.26 per cent, heated vaccines 0.15 per cent. Treatment paralysis was observed in only 6 cases. The incidence of paralysis for most vaccines corresponded closely with those given in the first report, while for dried or glycerinated vaccines the proportion fell from 1 in 464 to 1 in 5,302.

Non-Europeans run a much higher risk than Europeans—0.88 against 0.13. They are usually more severely bitten and on exposed parts of the body, treatment is commenced less promptly, and the biting animals prove more often positive. No evidence of special racial susceptibility has been discovered and there is no decisive evidence of the superiority of one method of treatment over another. An appendix gives the figures of the treatment at Sassari by Fermi from 1900 to 1930. Between 1900 and 1907, 700 persons were treated by the original Pasteur method, 2 of whom developed rabies, but they were both bitten on the bare skin of the head and in neither case was treatment commenced until the third week. From 1907 on, 3,974 persons have been treated by sero-vaccine and no case of rabies was developed. All persons treated were Europeans.

This volume ends with a survey of the Floods in China and the work undertaken by the Medical Director of Health against epidemics. Altogether the bulletin is most useful and we welcome its appearance.

# ASSOCIATION NEWS

61ST ANNUAL MEETING, WASHINGTON, D. C.

## SCIENTIFIC TRIPS

THE Association meeting this year offers an unusual opportunity for delegates not only to visit those places of national interest in the field of politics, religion, science and the arts, but to observe some of the governmental operations in the fields in which the members of this Association are peculiarly interested. Since the customary and popular points of interest are well known to many of the delegates and will be elsewhere completely described, this article is intended to set forth in brief fashion the inspection trips which will be available. The local committee has attempted to make these interesting generally to representatives of all of the sections.

For the public health statisticians the Division of Vital Statistics of the Bureau of the Census will demonstrate the operation of improved machinery for the mechanical tabulation and recording of vital statistics, and if time is available special motion picture films will be shown.

The public health engineers will be afforded an opportunity to visit the Dalecarlia filtration plant which includes the modern rapid filters, pumping station laboratory, hydro plant, and alum manufacture. Another trip includes the sewage pumping station and District incinerators where the mosquito control operations of the U. S. Public Health Service will be explained by these officials.

At the National Institute of Health can be seen a number of scientific projects including the study of nutrition with special reference to the prevention of pellagra, the investigation of typhus and Rocky Mountain spotted fever,

tularemia, and meningococcus meningitis. The Institute is also conducting immunological studies on diphtheria, tetanus, and botulinus, and is officially charged with the testing of certain commercial biological products.

Students of nutrition will be interested in the laboratories conducting research along this line in the Bureau of Chemistry and Soils, the Food and Drug Administration and the Bureau of Home Economics of the United States Department of Agriculture, as well as in the Bureau of Fisheries of the Department of Commerce, so far as marine products are concerned. These trips will also be extended to inspect the laboratories and technicological work carried on in the Bureau of Dairy Industry and the Bureau of Animal Industry of the Department of Agriculture.

The Army Medical Center is composed of the Walter Reed General Hospital, the Army Medical School, the Army Dental School, the Army Veterinary School, and training schools for dietitians, physiotherapy and occupational therapy aides. These schools are engaged in research and teaching and the medical and veterinary schools make many biological products on a large scale—typhoid vaccine, mallein, tuberculin, rabies vaccine, etc. All of these departments and schools will be open to inspection and those interested in a particular phase of laboratory investigation can arrange for special visits.

The extensive library of the Surgeon General is in the Army Medical Museum where it is planned to arrange a special exhibit showing a graphic history of public health in the Army, as well as some special laboratory apparatus.

Optional trips can be arranged for St. Elizabeths Hospital, the Naval Medical School, and for the Children's Bureau of the Department of Labor, the work of which will undoubtedly be of interest to the members who are concerned with vital statistics, child hygiene, public health education, and public health nursing.

A special trip immediately following the close of the meeting has been arranged to visit the School of Hygiene and Public Health of Johns Hopkins University at Baltimore. The activities of this institution should enlist the attention of epidemiologists and public health officers; in fact, the School of Hygiene should appeal to all interested in public health in its many aspects.

Other points of interest at Baltimore where provision will be made to receive

visitors are the Johns Hopkins Hospital, the Welch Memorial Library, and the laboratories of the State Department of Health and the City Department of Health.

Some of the Government buildings and laboratories will be within easy walking distance of the Willard Hotel and no special arrangements for transportation will be made. For places more remote, bus transportation is to be provided. The trip to Baltimore is a special trip, the cost of transportation to be defrayed by the individual members. Considerable reductions in round trip railroad and bus fares are available for those who will return to or through Washington.

Information in detail and the schedules for all inspection trips will be available at the registration desk.

#### SCIENTIFIC EXHIBIT OF THE INDUSTRIAL HYGIENE SECTION

FOR a number of years, exhibits have been an important feature of the Annual Meeting. Whether sponsored by commercial organizations or otherwise, they are always educational.

The Association has experimented with extensive popular health "shows" to which the public has been invited, notably at Chicago in 1928, and at Minneapolis in 1929. While these were well attended and occasioned favorable comment, the general feeling has been that exhibits entirely technical in character and designed to interest professional public health workers were more in keeping with the professional spirit of the American Public Health Association.

No one section of the organization has sponsored an exhibit up to this time. For the Washington meeting the Industrial Hygiene Section is arranging one to illustrate the progress and problems in preventive medicine in industry. There will be nine units of space covering more than 650 square feet.

The U. S. Bureau of Mines has been allotted four units to portray some present-day industrial hazards. Scientific apparatus will demonstrate methods of dust collection. Conditions induced by dust will also be demonstrated. These important exhibits are under the direction of Dr. R. R. Sayers.

Dr. Louis Schwartz of the U. S. Public Health Service has accumulated a mass of data as a result of his numerous studies of skin diseases in various industries. He draws on his experiences and records in arranging his exhibit on Industrial Dermatoses.

Recognizing the possible hazards resulting from the increasing use of certain toxic gases and volatile liquids in industry, the Committee on Exhibits has invited Dr. E. R. Hayhurst to demonstrate apparatus for determining the presence of poisonous gases. Part of Dr. Hayhurst's exhibit will deal with occupational diseases in Ohio, with special emphasis on Silicosis.

The American Social Hygiene Association's exhibit "Syphilis in Industry" will indicate the importance of syphilis as an industrial hazard, with suggestions as to what may be done about it. The subject will be approached under the following headings: Prevalence of syphilis in the general population, utilizing the most up-to-date statistical data available; the direct relation of syphilis to industry; illustrations of how syphilis is handled in representative concerns; suggestions for industry in remedying the situation; suggestions as to general community measures; and ways in which the American Social Hygiene Association is prepared to help industry.

Other demonstrations and displays of equal importance are in the process of being assembled.

One exhibit which falls outside the interests of the Industrial Hygiene Section, but which the committee considers

so worthwhile as to include, is sponsored by Dr. Henry F. Vaughan, Health Commissioner of Detroit. It deals with a coöperative community public health program, worked out between the local medical society and health department, as a means of increasing the number of persons reached through preventive medicine and health promotion activities by stimulating and making possible an increasingly greater practice of these services by private physicians.

Delegates to the Washington Annual Meeting are urged to inspect this first attempt of one section to interpret its work and aims to other public health specialists. There is much valuable information to be acquired by a study of the exhibits. It is hoped that the effort of the Industrial Hygiene Section will stimulate other groups in the Association to similar activity at meetings in the future.

## NEW MEMBERS

*The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.*

### *Health Officers Section*

Roy W. Benton, M.D., Shorewood, Wis., Health Commissioner  
J. D. Brook, M.D., Kent County Health Department, Grand Rapids, Mich., County Health Officer  
Oscar M. Craven, M.D., City Hall, Springfield, O., Director of Public Health  
Glenn C. Dowell, M.D., Carrollton, O., County Health Officer, Carroll County  
William C. Ellet, M.D., Department of Public Health, Benton Harbor, Mich., Director of Public Health  
Neil C. Geis, M.D., City Health Department, Casper, Wyo., City Health Officer  
Walter S. Holley, M.D., 2047 Calumet St., Toledo, O., Commissioner of Health  
Charles F. Nelson, M.D., Health Department, Beverly Hills, Calif., Health Officer  
William P. Parker, M.D., Davidson County Health Department, Nashville, Tenn., Assistant Health Officer  
H. H. Savage, M.D., City Health Department, Ogden, Utah, City Physician  
Lawrence J. Smith, M.D., Department of

Health, Warwick, R. I., Commissioner of Health

Harold P. Sullivan, M.D., 4751 Madison St., Chicago, Ill., Director of Health Service, Chicago Fire Department

Dr. Julio Vinięra, Jr., Avenida Morelos 32, Cuernavaca, Morelos, Mex., Director of Health

### *Public Health Engineering Section*

John A. Caraway, Health Department, Union City, Tenn., Sanitary Officer

John B. Gordon, District Building, Washington, D. C., Director of Sanitary Engineering, District of Columbia

Dr. Karl Imhoff, Ruhr Verband 37, Kronprinzen St., Essen, Germany, Sanitary Engineer (Assoc.)

Paul W. Mack, Metropolitan Water District, Manila, P. I., Manager and Chief Engineer  
C. H. Mock, Elizabethton, Tenn., Sanitary Inspector

James O. Myers, 906 Bigley Ave., Charleston, W. Va., Inspector, Kanawha County Health Unit

George G. Nasmith, Ph.D., 1130 Bay St., Toronto, Ont., Consulting Engineer  
L. R. Stockman, Box 635, Baker, Ore., Sanitary Engineer

#### *Laboratory Section*

Henri L. Berard, Ph.D., Provincial Dairy School, St. Hyacinthe, P. Que., Dairy Bacteriologist  
Hugh E. Eagan, 1418 15 St., Huntington, W. Va., Milk Inspector  
Lucille Watt, Box 268, Tuscaloosa, Ala., Director, Tuscaloosa Branch Laboratory

#### *Industrial Hygiene Section*

Katherine A. Rinis, 511 W. 186 St., New York, N. Y., Medical and Industrial Social Service

#### *Food and Nutrition Section*

Arthur K. Besley, Ph.D., 20 Monroe Ave., Riverdale, Md., Associate Bacteriologist, Bureau of Animal Industry, U. S. Dept. of Agriculture  
Gertrude S. Smith, 2694 University Ave., St. Paul, Minn., Acting Secretary, Twin City Unit, National Dairy Council

#### *Child Hygiene Section*

Marietta Catalano, M.D., 115 School St., Buffalo, N. Y., Assistant Medical School Examiner  
Pilar H. Lira, M.D., Apartado 679, Mexico, D. F., Mex., Director, Child Hygiene Division, Mexican Rural Health Service  
Charles E. McLean, M.D., 443 Sammon Ave., Toronto 6, Ont., Medical Officer of Health, Township of East York

#### *Public Health Education Section*

Lillian B. Davis, Sc.D., 1245 N. Broadway, Baltimore, Md., Supervisor of Health Education, Department of Education  
Florence J. Fiske, 440 S. Burdick St., Kalamazoo, Mich., Executive Secretary, Kalamazoo County Tuberculosis Assn.  
John H. Graves, M.D., 977 Valencia St., San Francisco, Calif., President, State Bd. of Health

Helen M. Hackett, R.N., 26 Lynde St., Boston, Mass., Consultant in Public Health Nursing, Dept. of Public Health  
J. B. Hock, R.N., 3612 North 17 St., Philadelphia, Pa. (Assoc.)  
Thomas T. McKinney, M.D., 2401 Emerson St., Denver, Colo., Medical Director, American Woodmen Society  
Alexander E. Nash, 140 W. Medical Bldg., Ann Arbor, Mich., Student (Assoc.)

#### *Public Health Nursing Section*

Ruth W. Hubbard, 1340 Lombard St., Philadelphia, Pa., Director, Visiting Nurse Society  
Margaret L. Jackson, 1409 Pennock Ave., Nashville, Tenn., Field Nurse, Davidson County Health Dept.  
Jane N. Laib, 3523 Wabash Ave., Baltimore, Md., Director, Bureau of Nursing, Health Dept.  
Mildred May, R.N., State Health Department, Nashville, Tenn., Public Health Nurse  
Caroline F. Reitz, R.N., R.D. No. 3, Brookville, Pa., Public School Nurse

#### *Epidemiology Section*

Rulx Leon, M.D., National Public Health Service, Port-au-Prince, Haiti, Director General  
Ralph E. Wheeler, M.D., U. S. Public Health Service, Ellicottville, N. Y., Epidemiologist

#### DECEASED MEMBERS

C. Hampson Jones, M.D., Baltimore, Md., Elected Member 1915, Fellow 1922  
Howard H. Bell, M.D., St. Louis, Mo., Elected Member 1928  
George H. Fox, M.D., Binghamton, N. Y., Elected Member 1920  
Walter T. Fuller, M.D., Dorchester, Mass., Elected Member 1920  
Edwin E. Hubbard, M.D., Dearborn, Mich., Elected Member 1929  
Arthur Kendrick, Brighton, Mass., Elected Member 1912  
Alma Taylor, R.N., Norwood, Mass., Elected Member 1921

#### ADDITIONAL APPLICANTS FOR FELLOWSHIP \*

HEALTH OFFICERS' SECTION—A. N. Crain, M.D., Phoenix, Ariz., William E. Donahoe, M.D., Sioux Falls, S. D., Peel M. Payne, M.D., Napoleonville, La.  
CHILD HYGIENE SECTION—Esther L. Richards, M.D., Baltimore, Md., Harold C. Stuart, M.D., Boston, Mass., Dorothy Worthington, M.D., White Plains, N. Y.

PUBLIC HEALTH EDUCATION SECTION—Melvin P. Isaminger, D.P.H., Corvallis, Ore.  
PUBLIC HEALTH NURSING SECTION—Mary J. Dunn, B.S., Nashville, Tenn.  
EPIDEMIOLOGY SECTION—Lee S. Huizenga, M.D., Jukao, Kiangsu, China.

\* See August JOURNAL, p. 847.

## NEW OFFICERS OF WESTERN BRANCH A.P.H.A.

DR. A. L. BEAGHLER was elected President of the Western Branch A.P.H.A. at the June meeting. He has been active in the affairs of the Western Branch for the past several years, and has been Vice-President for the past year. Dr. Beaghlér has been Director of Health Service for the Denver Public Schools since 1921, where he became nationally known in the field of school health work.

Dr. J. L. Pomeroy, Health Officer of Los Angeles County, became President-Elect.

Other officers elected were: *Vice-Presidents*—A. N. Crain, M.D., of Phoenix, Ariz.; Mrs. Saidie Orr-Dunbar, of Portland, Ore.; John J. Sippy, M.D., of Stockton, Calif. *Secretary*—W. P. Shepard, M.D., of San Francisco, Calif. *Treasurer*—W. F. Higby, of San Francisco, Calif.

## CONSTITUTIONAL CHANGES, WESTERN BRANCH

CERTAIN amendments have been made in the Constitution and By-Laws of the Western Branch. The following gives the present reading of the altered sections:

*Article IV (Constitution)**Officers*

The officers of the Western Branch, American Public Health Association, shall be Fellows of the Western Branch, American Public Health Association, and shall consist of a President, President-Elect, three Vice Presidents, a Secretary, and a Treasurer. The officers shall be elected by written ballot of the Active Members and Fellows present and voting at Annual Meeting as provided for in this article and in the By-Laws. The President-Elect shall serve as such from the close of the Annual Meeting at which he was elected to the close of the next Annual Meeting when he shall

automatically become President. As President he shall serve to the close of the next succeeding Annual Meeting. Officers shall serve from the close of the Annual Meeting when elected until the close of the next Annual Meeting; and all officers shall serve in any case until their successors are elected and qualified. A majority vote of those voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained.

*Article III (By-Laws)*

## (addition)

9. To appoint each year a representative on the Governing Council of the American Public Health Association, in accordance with Article III, Paragraph A, Item 6, of the Constitution of the American Public Health Association.

# PRELIMINARY PROGRAM OF THE SIXTY-FIRST ANNUAL MEETING

## AMERICAN PUBLIC HEALTH ASSOCIATION

*Washington, D. C., October 24-27, 1932*

THE Annual Meeting Program Committee presents the preliminary program of the scientific sessions of the Sixty-first Annual Meeting of the American Public Health Association and information concerning meetings of related organizations.

Scientific trips are listed on page 944. The next issue of the JOURNAL will give details regarding entertainment.

The complete program of the Institute on Health Education to be held October 22, 23, and 24, will be found on pages 971-972.

Since the following program cannot be considered definite in every respect now, delegates are urged to consult the Final Program, available at the Registration Desk in the Willard Hotel at the time of the meeting. All meetings, unless otherwise stated, will be held in the Willard Hotel.

*Monday, 9:30 A.M.*

### HEALTH OFFICERS

#### *First Session—Small Ball Room*

**Housing of Health Departments** (Report of the Committee on Business Management). I. F. THOMPSON, M.D., Commissioner of Health, Racine, Wis.

*Discussion.* ROBERT H. RILEY, M.D., State Commissioner of Health, Baltimore, Md., and JOHN P. KOEHLER, M.D., Commissioner of Health, Milwaukee, Wis.

**Vital Statistics and the Health Officer.** GEORGE B. L. ARNER, PH.D., Columbia University, New York, N. Y.

*Discussion.* SHIRLEY W. WYNNE, M.D., Commissioner of Health, New York, N. Y.

**Heart Disease and Public Health.** ALFRED E. COHN, M.D., The Hospital of the Rockefeller Institute for Medical Research, New York, N. Y.

*Discussion.* CHARLES F. WILINSKY, M.D., Deputy Commissioner, Child Hygiene Division, Department of Health, Boston. Mass.

**Getting Good Spirit in a Health Department Staff.** E. T. HANLEY, M.D., Seattle, Wash.

### VITAL STATISTICS

#### *First Session—Gridiron Room*

**Report of the Committee on Registration Affairs.** *Chairman,* T. F. MURPHY, M.D., Chief Statistician for Vital Statistics, Bureau of the Census, Washington, D. C.

*Monday, 9:30 A.M.*

## VITAL STATISTICS (Cont.)

### *First Session—Gridiron Room*

**The County Health Officer and Vital Statistics.** F. M. REGISTER, M.D., Director of Public Health, Goldsboro and Wayne County, Goldsboro, N. C.

**Precaution When Filing Deferred Certificates.** STEWART G. THOMPSON, D.P.H., Director, Division of Vital Statistics, State Board of Health, Jacksonville, Fla.

**The Occurrence, Physical Signs, and Significance of Pulmonic Systolic Murmurs in Adolescent Boys.** JEROME MEYERS, M.D., Department of Health, New York, N. Y.

**A Study of Resident Tuberculosis Mortality in New York State.** ELIZABETH PARKHURST, Senior Statistician, Division of Vital Statistics, State Department of Health, Albany, N. Y.

**Report of the Committee on Forms and Methods of Statistical Practice.** *Chairman,* A. W. HEDRICH, Sc.D., Associate in Biostatistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

## INDUSTRIAL HYGIENE

### *First Session—Cabinet Room*

**The Possibilities of Industrial Medical Service.** C.-E. A. WINSLOW, Dr.P.H., *Chairman*, Industrial Hygiene Section, Yale University, New Haven, Conn.

**Lead Poisoning Legislation.** FREDERICK L. HOFFMAN, LL.D., Prudential Insurance Company of America, Newark, N. J.

*Discussion.* SIR THOMAS OLIVER, Newcastle upon Tyne, England.

**Studies in Lead Excretion.** ROBERT KEHOE, M.D., College of Medicine, Cincinnati, O.

**Prevention of Lead Poisoning in Industry.** GEORGE H. GEHRMANN, M.D., Wilmington, Del.

**The Relative Susceptibility of Men and Women to Occupational Diseases.** CAREY P. MCCORD, M.D., Health Conservancy Laboratories, Cincinnati, O.

## CHILD HYGIENE

### *First Session—Large Ball Room*

#### *Research Session*

**Social and Economic Factors Influencing the Use of Preventive Medical Service for Preschool Children.** MAHEW DERRYBERRY, Research Assistant, Committee on Medical Care for Children, White House Conference on Child Health and Protection, New York, N. Y.

**A Suggested Method of Computing and Standardizing the Maternal Mortality Rate.** ROBERT J. LOWRIE, M.D., Adjunct Attending Obstetrician, Manhattan Maternity Hospital Dispensary, New York, N. Y.

**Sleep Patterns of Children.** SAMUEL RENSBAW, Ph.D., Associate Professor, Experimental Psychology, College of Education, Ohio State University, Columbus, O.

*Monday, 9:30 A.M.*

### CHILD HYGIENE (Cont.)

*First Session—Large Ball Room*

Some Outcomes from a Study of the Effects of School Health Programs on Children. RAYMOND FRANZEN, PH.D., Research Director, School Health Study, American Child Health Association, New York, N. Y.

*Monday, 12:15 P.M.*

### PUBLIC HEALTH EDUCATION

*Luncheon Session—Fairfax Room*

#### HEALTH BULLETINS

*Presiding:* BERTRAND BROWN, Director, Division of Publications, Milbank Memorial Fund, New York, N. Y.

What Health Departments Do About Health Education. JOHN HALL, American Public Health Association, New York, N. Y.

### PUBLIC HEALTH NURSING

*Luncheon Session—Rose Room, Washington Hotel*

*Monday, 2:30 P.M.*

### FOOD AND NUTRITION

*First Session—Cabinet Room*

Preservatives in Fruit Products. H. M. LANCASTER, Chief Dominion Analyst, Department of Pensions and National Health, Ottawa, Ont.

Dehydration of Foods. PROFESSOR SAMUEL C. PRESCOTT, Department of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

Health Value of Fruit Juice Beverages. WALTER H. EDDY, PH.D., Teachers College, Columbia University, New York, N. Y.

Nutritive Value of Cranberries. CARL R. FELLERS, PH.D., Massachusetts State College, Amherst, Mass.

Report of the Committee on Cereals and Their Products. *Chairman*, F. C. BLANCK, PH.D., U. S. Bureau of Chemistry and Soils, Washington, D. C.

Report of the Committee on Nutritional Problems. *Chairman*, PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

The Bacterial Content of Frosted Hamburg Steak. LAWRENCE P. GEER, and ERNEST SMITH, Birdseye Laboratories, Gloucester, Mass.

A New Syndrome Produced by Oxidizing Fat in the Diet. DOROTHY V. WHIPPLE, M.D., Pediatric Department, University of Pennsylvania, Philadelphia, Pa.

*Monday, 2:30 P.M.*

## PUBLIC HEALTH NURSING

*First Session—Rose Room, Washington Hotel*

(Continuation of Luncheon Session)

**Childhood Tuberculosis.** EUGENE L. OPIE, M.D., The Henry Phipps Institute, Philadelphia, Pa.

### *Discussion:*

**Health Officer.** R. M. ATWATER, M.D., DR.P.H., Commissioner of Health, Cattaraugus County Health Department, Olean, N. Y.

**School Physician.** L. W. CHILDS, M.D., Supervisor, Health Service, Bureau of Physical Welfare, Board of Education, Cleveland, O.

**Public Health Nurse.** VIOLET HODGSON, R.N., Assistant Director, National Organization for Public Health Nursing, New York, N. Y.

### *General Discussion.*

## EPIDEMIOLOGY

*First Session—Sun Room, Washington Hotel*

**Epidemiological Methods in the Control of Syphilis and Gonorrhea.** WILLIAM MUNSON, M.D., State Department of Health, Albany, N. Y.

**Typhus-Spotted Fever in Maryland.** ROBERT H. RILEY, M.D., State Health Officer, and C. N. HALLIDAY, M.D., State Department of Health, Baltimore, Md.

**The Epidemiology of the Typhus-Spotted Fever Group in the Eastern Part of the United States.** A. RUMREICH, M.D., P. A. Surgeon, U. S. Public Health Service, Washington, D. C.

**The Neutralization of Poliomyelitis Virus by the Serum of Liberian Negroes.** N. PAUL HUDSON, M.D., and EDWIN H. LENNETTE, Department of Hygiene and Bacteriology, University of Chicago, Chicago, Ill.

**The Epidemiology of Complications of Smallpox Vaccination.** CHARLES E. ARMSTRONG, M.D., Surgeon, U. S. Public Health Service, Washington, D. C.

**An Analysis of New York State Typhoid Carrier Control.** HERMAN F. SENFTNER, M.D., DR.P.H., and FRANK E. COUGHLIN, M.D., DR.P.H., State Department of Health, Albany, N. Y.

## PUBLIC HEALTH EDUCATION

*First Session—Large Ball Room*

### HEALTH MOTIVATION

**What to Believe.** R. M. ATWATER, M.D., DR.P.H., Commissioner of Health, Cattaraugus County Health Department, Olean, N. Y.

**Principles of Motivation.** BENJAMIN C. GRUENBERG, New York, N. Y., and E. S. ROBINSON, M.D., PH.D., Professor of Psychology, Institute of Human Relations, Yale University, New Haven, Conn.

Monday, 2:30 P.M.

## LABORATORY

*Session 1A\*—Medical Sub-Session—Fairfax Room*

*Presiding:* ANNA W. WILLIAMS, M.D., *Vice-Chairman*, Laboratory Section.

*Section Business* (In Session 1B\*).

**A Study of Lobar Pneumonia in Massachusetts: Methods and Results of Pneumococcus Type Determination, 1931-1932.** RODERICK HEFFRON, M.D., and FLORENCE M. VARLEY, Pneumonia Study and Service, Department of Public Health, Boston, Mass.

**A Test for Reaction-Producing Substances in Concentrated Antipneumococcal Serum.** L. A. BARNES, PH.D., Antitoxin and Vaccine Laboratory, State Department of Public Health, Boston, Mass.

**A Test for the Value of Antipneumococcus Serum in Rabbits.** KENNETH GOODNER, PH.D., The Hospital of the Rockefeller Institute for Medical Research, New York, N. Y.

**An Experimental and Clinical Comparison Between Convalescent Serum and Non-Convalescent Serum in Poliomyelitis.** MAURICE BRODIE, M.D., Department of Bacteriology, McGill University, Montreal, Que.

**Properties of Blood Serums Reactivating Completely Neutralized Meningococcus Toxic Substances.** GREGORY SHWARTZMAN, M.D., Laboratories of the Mount Sinai Hospital, New York, N. Y.

**The Shwartzman Phenomenon: Factors Complicating Its Use in Testing Antimeningococcal Serums.** ANNA M. PABST and SARA E. BRANHAM, PH.D., National Institute of Health, Washington, D. C.

**Titration of the Neutralizing Potency of Antimeningococcus Serum by the Phenomenon of Local Skin Reactivity.** GRACE SICKLES, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

## LABORATORY

*Session 1B\*—Sanitation Sub-Session—Gridiron Room*

### SYMPOSIUM ON STANDARD METHODS

*Presiding:* M. H. MCCRADY, *Chairman*, Laboratory Section.

*Section Business.*

**Some Proposed Procedures for the Presumptive Test in the Determination of the Coli-Aerogenes Group in Water.** C. T. BUTTERFIELD, U. S. Public Health Service, Cincinnati, O.

**Standardization of the Wassermann Test and Allied Procedures.** RUTH GILBERT, M.D., Division of Laboratories and Research, State Department of Health, Albany, N. Y.

**Report of the Committee on Standard Methods.** *Chairman*, R. G. PERKINS, M.D., Wakefield, R. I.

**Shellfish Analysis and the Problems Involved.** FREDERICK P. GORHAM, Brown University, Providence, R. I.

\* Session 1A—Medical Sub-Session in Fairfax Room, and Session 1B—Sanitation Sub-Session in Gridiron Room, meeting concurrently.

*Monday, 2:30 P.M.*

### LABORATORY (Cont.)

*Session 1B \*—Sanitation Sub-Section—Gridiron Room*

#### Standardization of Diagnostic Procedures and Reagents:

**The Bacteriology of the Intestinal Pathogens.** LEON C. HAVENS, M.D., State Department of Health, Montgomery, Ala.

**Agglutination in the Diagnosis of Enteric Disease.** RUTH GILBERT, M.D., and MARIAN B. COLEMAN, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

**Standardization of Diagnostic Reagents.** JOHN F. NORTON, Ph.D., Department of Health, Detroit, Mich.

#### *Discussion.*

**Open Forum on Bacteriological Methods for Milk Analysis.** ROBERT S. BREED, Ph.D., New York State Agricultural Experiment Station, Geneva, N. Y.

*Discussion opened by* N. J. HOHL, Bureau of Milk Sanitation, State Department of Health, Albany, N. Y.

---

\* Session 1A—Medical Sub-Session meeting concurrently in Fairfax Room.

### PUBLIC HEALTH ENGINEERING SECTION AND CONFERENCE OF STATE SANITARY ENGINEERS

*Joint Session—Small Ball Room*

**Report of the Joint Committee on Rural Sanitation.** *Chairman,* H. B. HOMMON, Sanitary Engineer, U. S. Public Health Service, San Francisco, Calif.

**Sanitation of Bathing Places** (Report of the Joint Committee on Swimming Pools and Bathing Places). *Chairman,* W. J. SCOTT, Director, Bureau of Sanitary Engineering, State Department of Health, Hartford, Conn.

**High Temperature—Short Time Pasteurization** (Combined Report from Conference Committee on Milk Sanitation and Section Committee on Milk Supply). *Chairman,* C. A. HOLMQUIST, Director, Division of Sanitation, State Department of Health, Albany, N. Y.

**Chemistry of Chlorination.** DR. FRANZ C. SCHMELKES, Assistant Director of Research, Wallace and Tiernan Company, Newark, N. J.

*Monday, 6:30 P.M.*

### PUBLIC HEALTH EDUCATION

*Dinner Session—Fairfax Room*

Closed session—for Fellows and members of the Section only.

*Section Business.*

*Monday, 8:00 P.M.*

## FIRST GENERAL SESSION

*Large Ball Room*

**Invocation.** RIGHT REVEREND JAMES E. FREEMAN, Bishop of Washington.

### Addresses of Welcome.

WILLIAM C. FOWLER, M.D., Health Officer of the District of Columbia, and Chairman of the Local Committee.

RAY LYMAN WILBUR, M.D., Secretary of the Interior.

DR. LUTHER H. REICHELDERFER, President, Board of Commissioners, District of Columbia.

### Address of the President of the American Public Health Association.

LOUIS I. DUBLIN, PH.D., Third Vice President and Statistician, Metropolitan Life Insurance Company, New York, N. Y.

*Reception and Dancing.*

*Tuesday, 9:30 A.M.*

## LABORATORY

*Session 2A\*—Medical Sub-Session—Fairfax Room*

**Presiding:** ANNA W. WILLIAMS, M.D., *Vice Chairman*, Laboratory Section.

### Laboratory Diagnosis of Tuberculosis Using Vitamin Deficient Animals.

JAMES STEVENS SIMMONS, M.D., Department of Bacteriology, U. S. Army Medical School, Washington, D. C.

**Study of Rocky Mountain Fever (Eastern Type) in Tennessee.** WILLIAM LITTERER, M.D., Division of Laboratories, State Department of Public Health, Nashville, Tenn.

**The Laboratory Diagnosis of Typhus Fever and Spotted Fever.** L. F. BADGER, M.D., National Institute of Health, Washington, D. C.

**A Bacteriological Study of Dysentery in Henrico County, Va.** G. FOARD MCGINNES, M.D., A. L. MACLEAN, M.D., and FORREST SPINDLE, State and County Departments of Health, Richmond, Va.

**Laboratory Diagnosis of Relapsing Fever and of Rat Bite Fever.** EDWARD FRANCIS, M.D., National Institute of Health, Washington, D. C.

**Laboratory Aids in the Diagnosis and Serum Therapy of Pneumococcus Pneumonia.** ALBERT B. SABIN, M.D., Department of Bacteriology and Immunology, New York University and Bellevue Hospital Medical College, New York, N. Y.

**Rheumatic Diseases and Sore Throat with Reference to Hemolytic Streptococci.** I. PILOT, M.D., and D. J. DAVIS, M.D., College of Medicine, University of Illinois, Chicago, Ill.

**The Adjustment of the Hydrogen Ion Concentration of Loeffler's Medium for the Diagnosis of Diphtheria.** C. A. STUART, PH.D., FREDERICK P. GORHAM, and R. M. PIKE, Biological Laboratory, Brown University, Providence, R. I.

**Value of Culture Tests in the Diagnosis of Diphtheria.** H. M. HATHFIELD, M.D., and A. G. MANN, Bureau of Laboratories, Department of Health, New York, N. Y.

\* Session 2B—Sanitation Sub-Session meeting concurrently in T-Room, Washington Hotel.

*Tuesday, 9:30 A.M.*

## LABORATORY

*Session 2B \*—Sanitation Sub-Session—T-Room, Washington Hotel*

*Presiding: M. H. McCrady, Chairman, Laboratory Section.*

**The Relation of the Actinic Intensity of Sunshine to Minimal Wave Length.**

GERALD L. HOEFT, and FRANCES DEYOUNG, Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

**Certain Relationships of Leucocytes and Streptococci to Mastitis.** G. J.

HUCKER, PH.D., New York State Agricultural Experiment Station, Geneva, N. Y.

**Bacteriological Milk Analysis: New York State's Supplement to "Standard Methods."** F. L. SCHACHT, PH.D., and A. H. ROBERTSON, PH.D., State Department

of Agriculture and Markets, Albany, N. Y.

**Standard Methods of Examining Powdered Milk and Its Allied Products.**

P. S. PRICKETT, PH.D., Mead Johnson & Company, Evansville, Ind.

**A Study of Bacteriological Methods of Testing and Means of Disinfecting Water with Chlorine, with Particular Reference to Swimming Pool Water.**

W. L. MALLMANN, Department of Bacteriology, Engineering Experiment Station, Michigan State College, East Lansing, Mich., and WILLIAM H. CARY, JR., Department of Health, Detroit, Mich.

**The Treatment of Water by Colloidal Silver, Silver Nitrate, and Certain Silvered Materials.** JAMES GIBBARD, Laboratory of Hygiene, Department of

Pensions and National Health, Ottawa, Ont.

**Present Status of Handling Water Samples and Comparison of Bacteriological Analyses Under Varying Temperature and Holding Conditions with Special Reference to the Direct Method.** ELPREDA L. CALDWELL and LELAND

W. PARR, PH.D., Field Research Laboratory, State Department of Health, Andalusia, Ala.

---

\* Session 2A—Medical Sub-Session meeting concurrently in Fairfax Room

## PUBLIC HEALTH ENGINEERING AND INDUSTRIAL HYGIENE SECTIONS

*Joint Session—Small Ball Room*

### SYMPOSIUM ON AIR HYGIENE

**Sunlight and Health.** HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

**Loss of Actinic Sunshine as a Health Problem of Cities.** FRED O. TONNEY, M.D., Assistant Commissioner in Charge of Research, Department of Health, Chicago, Ill.

**On the Bacterial Behavior of Air.** W. F. WELLS, Harvard Engineering School, Cambridge, Mass.

**Air Conditioning with Relation to Comfort, Health and Efficiency.** EMERY R. HAYHURST, M.D., PH.D., Consulting Industrial Hygienist, Columbus, O.

**The Scientific Basis of Ventilation Standards.** LEONARD GREENBURG, M.D., PH.D., Yale University, New Haven, Conn.

*Tuesday, 9:30 A.M.*

## CHILD HYGIENE AND PUBLIC HEALTH NURSING SECTIONS AND AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

*Joint Session—Large Ball Room, Gridiron Room, and Cabinet Room*

*Presiding:* WILLIAM A. HOWE, M.D., State Medical Inspector of Schools, and Secretary, American Association of School Physicians, Albany, N. Y.

Round Table Discussions

Three Separate Subjects Each in a Room

**Relative Merits of Three School Dental Programs as Outlined by Dr. Alfred Walker at the Montreal Meeting of the American Public Health Association.** *Group Leader.* GEORGE H. WANDEL, D.D.S., Supervisor, Bureau of Public Relations, American Dental Association, Chicago, Ill.

**The Functions of the School Physician, Nurse, Teacher, and Principal in a School Health Program.** *Group Leader.* HARRIET FULMER, R.N., Supervisor, Rural Nurses, Cook County, Chicago, Ill.

**Community Responsibility for Medical Service to Infants and Preschool Children.** *Group Leader.* DONALD B. ARMSTRONG, M.D., Third Vice President, Metropolitan Life Insurance Company, New York, N. Y.

*General Summary in Large Ball Room.*

## PUBLIC HEALTH EDUCATION

*Second Session—Rose Room, Washington Hotel*

### CLINIC ON PRINTED MATTER

**Clinician—**H. E. KLEINSCHMIDT, M.D., Director, Health Education, National Tuberculosis Association, New York, N. Y., assisted by RAYMOND S. PATTERSON, PH.D., Life Conservation Service, John Hancock Mutual Life Insurance Company, Boston, Mass.

*Tuesday, 12:15 P.M.*

## INDUSTRIAL HYGIENE

*Luncheon Session—Fairfax Room*

**Address.** SIR THOMAS OLIVER, Newcastle upon Tyne, England

**Reports of Committees.**

**Rehabilitation of the Industrial Disabled (*Motion Picture*).**

## CHILD HYGIENE

*Luncheon Session—Small Ball Room*

*Tuesday, 2:30 P.M.*

## VITAL STATISTICS

### *Second Session—Gridiron Room*

#### *Section Business.*

Report of the Committee on Registration of Births of Illegitimate and Adopted Children. *Chairman*, SHELDON L. HOWARD, State Registrar, State Department of Health, Springfield, Ill.

Public Health in Porto Rico. MANUEL A. PEREZ, Chief, Bureau of Vital Statistics, Department of Health, San Juan, P. R.

The Vital Statistics of the United States 1900-1930: A Preliminary Study. WALTER F. WILLCOX, PH.D., Professor of Economics and Statistics, Cornell University, Ithaca, N. Y.

A Study of Mortality by Census Tracts in Cincinnati. FLOYD P. ALLEN, M.D., Associate Secretary, Public Health Federation, Cincinnati, O.

A Code for Indexing Statistical Tables. A. W. HEDRICH, Sc.D., Associate in Biostatistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Seasonal Distribution of Whooping Cough for Periods of High and Low Incidence. GATUS E. HARMON, M.D., Department of Hygiene and Bacteriology, School of Medicine, Western Reserve University, Cleveland, O.

## EPIDEMIOLOGY

### *Second Session—Fairfax Room*

A Study of 1300 Deaths from Measles. E. S. GODFREY, JR., M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y.

Epidemic Influenza: A Comparison of Symptomatology as Observed in a Major and in a Minor Epidemic. J. A. DOULL, M.D., and ANNA BAHLKE, Department of Hygiene and Bacteriology, Western Reserve University, Cleveland, O.

Diphtheria Studies in Detroit. HENRY F. VAUGHAN, D.P.H., Commissioner of Health, and DON W. GUDAKUNST, M.D., Department of Health, Detroit, Mich.

The Risk of Persons in Familial Contact with Pulmonary Tuberculosis. W. H. FROST, M.D., School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

The Results of a Survey of Trachoma Incidence in Tennessee and the Program of Accomplishment to Date. P. E. FAED, M.D., Trachoma Field Technician, State Department of Health, Nashville, Tenn., and C. E. RICE, M.D., P. A. Surgeon, Trachoma Prevention, U. S. Public Health Service, Rolla, Mo.

## MENTAL HYGIENE

### *Special Session—Large Ball Room*

*Presiding:* CHARLES F. WILINSKY, M.D., Deputy Commissioner, Child Hygiene Division, Department of Health, Boston, Mass.

Mental Health of the Preschool Child. IRA S. WILE, M.D., Assistant Pediatrician, Mount Sinai Hospital, New York, N. Y.

Mental Health of the School Child. ESTHER RICHARDS, M.D., Associate Professor of Psychiatry, Johns Hopkins Hospital, Baltimore, Md.

*Tuesday, 2:30 P.M.*

## MENTAL HYGIENE (Cont.)

*Special Session—Large Ball Room*

**Mental Health of the Adolescent.** WILLIAM A. WHITE, M.D., President, Institute of Mental Hygiene, Washington, D. C.

**Summarization.** CLARENCE M. HINCKS, M.D., General Director, National Committee for Mental Hygiene, New York, N. Y.

**The Aim and Accomplishments of a Health Center Mental Hygiene Program.** ELIZABETH ADAMSON, M.D., Psychiatrist, Bellevue-Yorkville Health Demonstration, New York, N. Y.

## PUBLIC HEALTH ENGINEERING

*First Session—Small Ball Room*

*Section Business.*

**Report of the Committee on Fellowship and Membership.** *Chairman,* LINN H. ENSLOW, Editor, *Water Works and Sewerage*, New York, N. Y.

**Report of the Committee on Public Health Engineering Manual.** *Chairman,* ARTHUR E. GORMAN, Engineer of Filtration, Department of Public Works, Chicago, Ill.

### SYMPOSIUM ON AIR HYGIENE (Continued)

**The Effects of Air Contaminants on the Natural Light of Cities.** H. B. MELLER, Head, and MARY E. WARGA, Industrial Fellow, Air Pollution Investigation, Mellon Institute of Industrial Research, Pittsburgh, Pa.

**Aerial Nuisances from the Refining and Burning of Petroleum Oils as a Public Health Problem.** STEPHEN DEM. GAGE, Consulting Engineer, Providence, R. I.

*Discussion.* EDWARD WRIGHT, Sanitary Engineer, State Department of Health, Boston, Mass.

**Smoke Abatement at Low Cost.** MORRIS M. COHN, Sanitary Engineer, Department of Public Works, Schenectady, N. Y.

**Noise and Its Relation to Health.** EDWARD F. BROWN, Director, Noise Abatement Commission, New York, N. Y.

**Progress Report of the Committee on Noise.** *Chairman,* C. R. COX, Assistant Sanitarian, State Department of Health, Albany, N. Y. (To be presented by title only.)

## FOOD AND NUTRITION

*Second Session—Cabinet Room*

**Report of the Committee on Fish and Shell Fish.** *Chairman,* ALBERT C. HUNTER, PH.D., U. S. Food and Drug Administration, Washington, D. C.

**The Vitamin Content of the Water Soluble Portion of Milk.** R. C. BENDER, PH.D., and GEORGE C. SUPPLEE, PH.D., Research Laboratories, The Dry Milk Company, Bainbridge, N. Y.

**Fumigation of Foodstuffs: Public Health Aspects of an Increasing Commercial Practice.** C. L. WILLIAMS, M.D., Senior Surgeon, U. S. Public Health Service, Washington, D. C.

**Metals and Their Relation to Public Health.** C. N. MYERS, M.D., and DINFORD THRONE, M.D., New York Skin and Cancer Hospital, New York, N. Y.

*Tuesday, 2:30 P.M.*

## FOOD AND NUTRITION (Cont.)

*Second Session—Cabinet Room*

**Health Hazards Involved in the Spraying of Fruits and Vegetables.** FREDERICK B. FLINN, PH.D., Associate Professor of Physiology, Columbia University, New York, N. Y.

**Report of the Committee on Meat and Meat Products.** *Chairman,* PAUL E. HOWE, PH.D., U. S. Bureau of Animal Industry, Washington, D. C.

**Comparative Nutritional Values of Oysters and Beef Liver and Other Dietary Supplements in Certain Dietary Deficiency States in Chickens.** H. D. PEASE, M.D., Pease Laboratories, New York, N. Y.

**Nutrition and the Present Economic Situation.** DR. LYDIA J. ROBERTS, *Chairman*, Department of Home Economics and Household Administration, University of Chicago, Chicago, Ill.

*Tuesday, 6:30 P.M.*

## PUBLIC HEALTH ENGINEERING

*Joint Dinner—Small Ball Room*

**Public Health Engineering Section and Conference of State Sanitary Engineers.** Annual Engineers' Stag Dinner Party.

## TRAINING AND PERSONNEL

*Dinner Session—Fairfax Room*

**Presiding:** CLAIR E. TURNER, DR.P.H., *Chairman*, Committee on Training and Personnel, Massachusetts Institute of Technology, Cambridge, Mass.

**The Current Work of the Committee.** CLAIR E. TURNER, DR.P.H.

**Possible Coöperation with the National Board of Medical Examiners.** W. S. LEATHERS, M.D., President, National Board of Medical Examiners, School of Medicine, Vanderbilt University, Nashville, Tenn.

**The Public Health Nursing Profession.** LILLIAN A. HUDSON, R.N., Department of Nursing Education, Teachers College, Columbia University, New York, N. Y.

**Professionalizing Public Health.** E. L. BISHOP, M.D., State Health Commissioner, Nashville, Tenn.

*Tuesday, 8:00 P.M.*

## MAINTAINING HEALTH EFFICIENCY IN TIMES OF DISTRESS

*Special Session—Large Ball Room*

A session devoted to a description of problems precipitated on health departments throughout the United States by the increased responsibilities and the reduced appropriations of a depression period, and how those problems have been met. No formal addresses. General discussion invited.

**Presiding:** LOUIS I. DUBLIN, PH.D., President, American Public Health Association, New York, N. Y.

Wednesday, 9:30 A.M.

## LABORATORY

*Session 3\*—Medical Sub-Session—Fairfax Room*

*Presiding:* M. H. McCrady, *Chairman*, Laboratory Section.

**The Clinical Value of the Presumptive Kahn Test.** TOMAS CAJIGAS, M.D., Clinical Pathological Laboratory, Washington, D. C.

**Choosing a Serum Test for Syphilis.** WILLIAM A. HINTON, M.D., Department of Clinical Research, Boston Dispensary and Wassermann Laboratory, State Department of Public Health, Boston, Mass.

**The Serology of Syphilis from the Standpoint of the Public Health Laboratory with Special Reference to Precipitation Methods.** JOHN A. KOLMER, M.D., DR.P.H., Department of Pathology and Bacteriology, Research Institute of Cutaneous Medicine, Temple University, Philadelphia, Pa.

**Recent Trends in Practical Luetic Serology and Their Relation to the Public Health Laboratory.** B. S. LEVINE, PH.D., Laboratory of Public Health Institute, Chicago, Ill. (To be presented by title only.)

**Some Observations on the Quantitative Kahn in the Various Stages of Syphilis.** JOHN M. McCANTS, M.D., Lieutenant Commander, Medical Corps, United States Navy, Norfolk Naval Hospital, Portsmouth, Va.

**The Agglutination Reaction in the Identification of Certain Pathogenic Funguses.** W. D. STOVALL, M.D., and ANNA BUBOLZ, State Laboratory of Hygiene, Madison, Wis.

**Yeast-like Funguses Found on the Skin and in the Intestines of Normal Individuals: A Survey of One Hundred Persons.** RHODA W. BENHAM, PH.D., Mycologist, Laboratory for Medical Mycology, College of Physicians and Surgeons, Columbia University, New York, N. Y.

**Necrobacillosis—A Clinical Entity.** FREDERICK W. SHAW, M.D., Department of Bacteriology and Clinical Pathology, Medical College of Virginia, Richmond, Va.

**The Effectiveness of Fungicides Upon Two Pathogenic Funguses.** CHESTER W. EMMONS, PH.D., Laboratory for Medical Mycology, College of Physicians and Surgeons, Columbia University, New York, N. Y.

## LABORATORY AND EPIDEMIOLOGY SECTIONS<sup>4</sup>

*Joint Session—Large Ball Room*

### SYMPOSIUM ON INCIDENCE, IDENTIFICATION AND SIGNIFICANCE OF BACTERIAL CARRIERS

*Presiding:* HAVEN EMERSON, M.D., *Chairman*, Epidemiology Section, and ANNA W. WILLIAMS, M.D., *Vice Chairman*, Laboratory Section.

**An Epidemiological Study of Diarrhea and Dysentery in Henrico County, Va.** G. FOARD MCGINNES, M.D., A. L. McLEAN, M.D., and FORREST SPINDLE, State and County Departments of Health, Richmond, Va.

**Hemolytic Streptococcus Antigens from Throats of Normal People Compared with Those from Beginning Pneumonias and Terminal Septicemias.** ANNA W. WILLIAMS, M.D., C. T. GURLEY, B. KULCHIN and N. STRYON, Bureau of Laboratories, Department of Health, New York, N. Y.

<sup>4</sup> Session 3—Medical Sub-Session, Laboratory Section, in Fairfax Room, and Joint Session of Laboratory and Epidemiology Sections in Large Ball Room, meeting concurrently.

Wednesday, 9:30 A.M.

## LABORATORY AND EPIDEMIOLOGY SECTIONS (Cont.)\*

*Joint Session—Large Ball Room*

**Epidemiological Significance of a Given Health Carrier Rate.** LLOYD AYCOCK, M.D., Department of Epidemiology, Harvard School of Public Health, Boston, Mass.

**Carriers in Whooping Cough.** TRAVIS P. BURROUGHS, M.D., Director, Bureau of Communicable Diseases, and EDMUND K. KLINE, D.P.H., Director of Laboratories, Cattaraugus County Department of Health, Olean, N. Y.

**Demonstration of Tubercle Bacilli in the Sputum, Feces, and Stomach Lavage of Suspected Tuberculous Children.** LUCY MISHULOW, Bureau of Laboratories, Department of Health, CAMILLE KERESZTURI, M.D., New York University Medical College, and DAVID HAUPTMAN, M.D., Department of Pediatrics, Sea View Hospital, New York, N. Y.

**Discussion.** WILLIAM H. PARK, M.D., Bureau of Laboratories, Department of Health, and BELA SCHICK, M.D., Pediatrician, Mount Sinai Hospital, New York, N. Y.

**Serological Diagnosis of Typhoid Carriers.** JOHN WYLLIE, D.P.H., Department of Preventive Medicine, Queen's University, Kingston, Ont.

**A Study of Typhoid Carriers.** LLOYD ARNOLD, M.D., Department of Bacteriology, University of Illinois, Chicago, Ill.

---

\* Session 3—Medical Sub-Session, Laboratory Section, meeting concurrently in Fairfax Room.

## PUBLIC HEALTH ENGINEERING

*Second Session—Sun Room, Washington Hotel*

**The Sanitary and Economic Aspects of Municipal Cleansing.** GEORGE A. SOPER, Great Neck, N. Y.

**Street Cleaning in Washington.** T. L. COSTIGAN, Superintendent of Street Cleaning, City Refuse Department, Washington, D. C.

**Incineration in Washington.** H. P. EDDY, JR., Metcalf and Eddy, Boston, Mass., and J. B. GORDON, Director of Sanitary Engineering, Engineering Department, Washington, D. C.

**Garbage Reduction Methods.** H. H. MATTHIESON, Sanitary Engineer, Department of Health, Los Angeles, Calif.

**Discussion.** E. E. BUTTERFIELD, M.D., Consulting Chemist, Forest Hills, N. Y.

**Progress Report of the Committee on Industrial Plant Sanitation.** *Chairman,* F. G. LEGG, Sanitary Engineer, Department of Health, Detroit, Mich. (To be presented by title only.)

**Purification of Beet Sugar Wastes.** MAX LEVINE, Ph.D., Department of Bacteriology, Iowa State College, Ames, Ia.

## VITAL STATISTICS

*Third Session—Gridiron Room*

### SYMPOSIUM ON VITAL STATISTICS REGISTRATION PROBLEMS

*Wednesday, 9:30 A.M.*

## HEALTH OFFICERS

### *Second Session—Small Ball Room*

**Health in the Philippines.** M. A. DELANEY, M.D., Brigadier-General, Medical Department, Assistant Surgeon-General, War Department, Washington, D. C.

*Discussion.* DON L. GRISWOLD, M.D., Consulting Epidemiologist, State Department of Health, Albany, N. Y.

**The Set Up, Functioning, and Administration of a Bureau of Tuberculosis in a City of 160,000.** HERBERT R. EDWARDS, M.D., Director, Bureau of Tuberculosis, Department of Health, New Haven, Conn.

*Discussion.* ALTON S. POPE, M.D., Director, Division of Tuberculosis, State Department of Health, Boston, Mass., and HUNTINGTON WILLIAMS, M.D., Director, Department of Health, Baltimore, Md.

**Physical Examination of Domestic Employees.** CHARLES V. CRASTER, M.D., Health Officer, Newark, N. J.

*Discussion.* H. L. AKRIDGE, M.D., Health Officer, Glynn County, Brunswick, Ga., and D. L. RICHARDSON, M.D., Commissioner of Health, Providence, R. I.

**Health Centers.** KENNETH WIDDEMER, Executive Officer, East Harlem Health Center, New York, N. Y.

## INDUSTRIAL HYGIENE

### *Second Session—Cabinet Room*

**Studies in Employee Effectiveness at the Western Electric Company.** CLAIR E. TURNER, DR.P.H., Massachusetts Institute of Technology, Cambridge, Mass.

**The Appraisal Form for Industrial Health Service.** L. D. BRISTOL, M.D., Medical Director, American Telephone and Telegraph Company, New York, N. Y.

**A Comprehensive Program of Industrial Hygiene for State Departments of Labor and Health.** BERNARD S. COLEMAN, Newark, N. J.

**A Study Made of 2500 Girls in a Continuation School in New York City.** SOPHIE RABINOFF, M.D., Bureau of Industrial and Adult Hygiene, Department of Health, New York, N. Y.

**Industrial Dermatoses.** LOUIS SCHWARTZ, M.D., U. S. Bureau of Mines, Washington, D. C.

## CHILD HYGIENE

### *Second Session—Rose Room, Washington Hotel*

#### *(Special Studies and Business Meeting)*

**Infant Mortality Study in Denver.** A. D. H. KAPLAN, PH.D., Director, Social Studies, Bureau of Business and Social Research, University of Denver, Denver, Colo.

**Infant Mortality Study in Cleveland.** RICHARD A. BOLT, M.D., DR P.H., Director, Cleveland Child Health Association, Cleveland, O.

**Report of the Committee to Study and Report on the Problem of Infant and Maternal Mortality.** *Chairman,* JULIUS LEVY, M.D., Consultant in Child Hygiene, State Department of Health, Trenton, N. J.

*Wednesday 9:30 A.M.*

### CHILD HYGIENE (Cont.)

*Second Session—Rose Room, Washington Hotel*

**Report of the Committee to Study White House Conference Recommendations.**

*Chairman, HAROLD H. MITCHELL, M.D., Staff Associate, Division of Research, American Child Health Association, New York, N. Y.*

*Discussion.*

*Section Business.*

### PUBLIC HEALTH EDUCATION

*Third Session—Hall of Nations, Washington Hotel*

#### CLINIC ON RADIO BROADCASTING

Representative Programs of the Playlet, Dialogue, and Monologue Types  
will be broadcast and criticised.

**Playlet Type—**FLORENCE M. BAUER, assisted by W. W. BAUER, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago, Ill.

**Dialogue Type—**JOHN L. RICE, M.D., Health Officer, and HERBERT F. HIRSCH, Executive Secretary, Cancer Control Committee, Department of Health, New Haven, Conn.

**Monologue Type—**HOWARD W. HAGGARD, M.D., Associate Professor of Applied Physiology, Yale University, New Haven, Conn.

**Critics:** W. W. PETER, M.D., DR.P.H., Cleanliness Institute, New York, N. Y., and PHILIP G. LOUCKS, Managing Director, National Association of Broadcasters, Washington, D. C.

*Wednesday, 12:15 P.M.*

### DIPHTHERIA PREVENTION

*Special Luncheon Session—Small Ball Room*

**Presiding:** GEORGE C. RUHLAND, M.D., Commissioner of Health, Syracuse, N. Y.

**Obstructions in the No-Diphtheria Path.** WILLIAM P. SHEPARD, M.D., Assistant Secretary, Metropolitan Life Insurance Company, San Francisco, Calif.

**Toxoid Versus Toxin-Antitoxin.** WILLIAM H. PARK, M.D., Bureau of Laboratories, Department of Health, New York, N. Y.

**Securing and Continuing Records of Immunizations Performed.** EDWARD S. GODFREY, JR., M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y.

**How State-wide Voluntary Health Associations Can Assist Official Agencies in Eradicating Diphtheria.** GEORGE J. NELBACH, Executive Secretary, State Committee on Tuberculosis and Public Health, New York, N. Y.

*Discussion.* HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich.

*Wednesday, 12:15 P.M.*

## FOOD AND NUTRITION

*Luncheon Session—Fairfax Room*

Address. CLYDE B. SCHUMAN, American Red Cross, Washington, D. C.

*Section Business.*

*Wednesday, 2:30 P.M.*

## PUBLIC HEALTH TEN STAR FINAL

*Special Session—Large Ball Room*

(A Symposium on the Current Work of the Ten Sections)

*Presiding:* MAZŮCK P. RAVENEL, M.D., University of Missouri, Columbia, Mo.

Address by the Presiding Officer.

**Laboratory Section**—GEORGE W. MCCOY, M.D., Director, National Institute of Health, Washington, D. C.

**Health Officers Section**—HUNTINGTON WILLIAMS, M.D., Director, Department of Health, Baltimore, Md.

**Vital Statistics Section**—EDWIN W. KOPF, Metropolitan Life Insurance Company, New York, N. Y.

**Public Health Engineering Section**—ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md.

**Industrial Hygiene Section**—ALICE HAMILTON, M.D., Assistant Professor, Industrial Medicine, Harvard School of Public Health, Boston, Mass.

**Food and Nutrition Section**—PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

**Child Hygiene Section**—JAMES F. ROGERS, M.D., Consultant in Hygiene and Specialist in Health Education, U. S. Department of the Interior, Washington, D. C.

**Public Health Education Section**—JAGO GALDSTON, M.D., Director, Medical Information Bureau, New York Academy of Medicine, New York, N. Y.

**Public Health Nursing Section**—HELEN LAMALLE, R.N., Superintendent of Nursing Service, Metropolitan Life Insurance Company, New York, N. Y.

**Epidemiology Section**—HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

*Wednesday, 8:00 P.M.*

## SECOND GENERAL SESSION

*Banquet—Large Ball Room*

Announcement of Awards.

The Western Branch, American Public Health Association. WILLIAM P. SHEPARD, M.D., Secretary, Western Branch, American Public Health Association, San Francisco, Calif.

*Dancing.*

*Thursday, 9:30 A.M.*

## LABORATORY

*Session 4A\*—Medical Sub-Session—Gridiron Room*

### SYMPOSIUM ON BACTERIAL DISSOCIATION

*Presiding:* RUTH GILBERT, M.D., Division of Laboratories and Research, State Department of Health, Albany, N. Y.

*Section Business.*

**The Dissociation of Bacterium Typhosus in Its Relation to the Production of Anti-typhoid Vaccine.** FRANCIS B. GRINNELL, M.D., Department of Bacteriology and Immunology, Harvard University Medical School, Boston, Mass.

**Some Variants of Bacillus Megatherium.** GEORGES KNAYSI, PH.D., Department of Dairy Industry, Cornell University, Ithaca, N. Y.

**A Study of the Reversion of Rough Variants.** G. M. MACKENZIE, M.D., VERNAL IRONS, PH.D., and HELEN FITZGERALD, The Mary Imogene Bassett Hospital, Coopers-town, N. Y.

**Dissociation of the Large Fusiform Bacillus.** DAVID T. SMITH, M.D., Duke University, Durham, N. C.

**Study of Variation in Erysipelas Strains.** SOPHIE SPICER, M.D., Bureau of Laboratories, Department of Health, New York, N. Y.

*Discussion.* STANHOPE BAYNE-JONES, M.D., School of Medicine and Dentistry, University of Rochester, Rochester, N. Y., and R. R. SPENCER, M.D., Surgeon, National Institute of Health, Washington, D. C.

**Parasitology in Relation to Public Health.** MAURICE C. HALL, PH.D., Zoological Division, Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

**The Advantages of Photo-Electric Over Visual Measurements as Exemplified by the Photo-Electric Scopometer.** WILLIAM G. EXTON, M.D., Laboratory and Longevity Service, The Prudential Insurance Company of America, Newark, N. J.

## LABORATORY

*Session 4B\*—Medical Sub-Session—T-Room, Washington Hotel*

*Presiding:* M. H. MCCRADY, Chairman, Laboratory Section.

*Section Business.* (In Session 4A\*)

**The Antigenic Value of Commercial Diphtheria Toxoids.** WILLIAM LEVIN, DR.P.H., Hygienic Laboratory, State Board of Health, and HELEN A. CARY, M.D., Medical Director, City Schools, Portland, Ore.

**Comparative Evaluation of Diphtheria Toxoid Preparations and Methods of Immunization.** JOHN D. MONROE, M.D., and V. K. VOLK, M.D., Oakland County Department of Health, Pontiac, Mich.

**The Effect of Tonsillectomy on the Schick Test and Dick Test.** WILLIAM H. PARK, M.D., Bureau of Laboratories, Department of Health, CAMILLE KERESZTURI, M.D., New York University Medical College, and OSCAR RIMSON, M.D., Fifth Avenue Hospital, New York, N. Y.

*Discussion.* BELA SCHICK, M.D., Pediatrician, Mount Sinai Hospital, New York, N. Y.

---

\* Session 4A—Medical Sub-Session in Gridiron Room, and Session 4B—Medical Sub-Session in T-Room, Washington Hotel, meeting concurrently.

Thursday, 9:30 A.M.

### LABORATORY (Cont.)

*Session 4B \*—Medical Sub-Section—T-Room, Washington Hotel*

**The Use of Concentrated Toxoid in Immunization Against Diphtheria.**  
WILLIAM EDWARD BUNNEY, PH.D., Bureau of Laboratories, State Department of Health, Lansing, Mich.

**Studies on Bacterial Activity in Various Levels of the Intestines of Monkeys and Dogs.** G. M. DACK, and ELIZABETH PETRAN, Department of Hygiene and Bacteriology, University of Chicago, Chicago, Ill.

**The Portals of Entry of Brucella Abortus in Guinea Pigs.** C. L. EVERSON, D.V.M., L. J. POELMA, D.V.M., A. L. BRUECKNER, V.M.D., and E. M. PICKENS, D.V.M., Department of Bacteriology and Pathology, University of Maryland, College Park, Md.

**A Study of Opsono-Cytophagic Activity of the Blood in Brucella Infection and Immunity in Man.** I. FOREST HUDDLESON, D.V.M., and HOWARD W. JOHNSON, D.V.M., Central Brucella Station, Michigan State Experiment Station, East Lansing, Mich.

---

\* Session 4A—Medical Sub-Session meeting concurrently in Gridiron Room.

## HEALTH OFFICERS AND PUBLIC HEALTH NURSING SECTIONS

*Joint Session—Large Ball Room*

### ADMINISTRATION OF PUBLIC HEALTH NURSING WORK AND THE RELATIONSHIP BETWEEN HEALTH OFFICER AND NURSE

*Presiding: Chairman Health Officers Section, GEORGE C. RUHLAND, M.D., Commissioner of Health, Syracuse, N. Y., and Chairman Public Health Nursing Section, HELEN LAMALLE, R.N., Superintendent of Nursing Service, Metropolitan Life Insurance Company, New York, N. Y.*

**Points of View of a Health Officer.** JACOB C. GEIGER, M.D., Health Officer, San Francisco, Calif.

**Points of View of a Supervisor of Nurses.** MARION W. SHEAHAN, Director, Division of Public Health Nursing, State Department of Health, Albany, N. Y.

**Points of View of a Bureau Chief.** DON W. GUDAKUNST, M.D., Director, School Health Service, Department of Health, Detroit, Mich.

**Points of View of a Field Nurse.** MARGARET D. WESTBROOK, City Nurse, Ogdensburg, N. Y.

## PUBLIC HEALTH ENGINEERING

*Third Session—Fairfax Room*

**Public Health Engineering Functions of City Health Departments (Report of the Committee on Record Forms).** *Chairman, I. W. MENDELSON, Washington, D. C.*

**Chlorine in Sewage Disposal (Report of the Committee on Sewage Disposal).** *Chairman, LANGDON PEARSE, Sanitary Engineer, Sanitary District of Chicago, Chicago, Ill.*

*Thursday, 9:30 A.M.*

## PUBLIC HEALTH ENGINEERING (Cont.)

*Third Session—Fairfax Room*

The Romance of the "Specialist" (Report of the Committee on Promotion of Environmental Sanitation). *Chairman*, V. M. EHLERS, Chief Sanitary Engineer, State Department of Health, Austin, Tex.

Taste and Odor Removal Processes (Report of the Committee on Water Supply). *Chairman*, J. R. BAYLIS, Physical Chemist, Department of Public Works, Chicago, Ill.

Occurrences of Fluorine in Water (Report of the Sub-Committee on Ground Water). *Sub-Chairman*, W. S. JOHNSON, State Board of Health, Jefferson City, Mo.

The Application of the Principles of Water Purification to Swimming Pool Control Programs. A. H. FLETCHER, Sanitary Engineer, Department of Health, Memphis, Tenn., and A. E. CLARK, Associate Sanitary Engineer, State Department of Health, Nashville, Tenn.

Progress Report of the Committee on Waterways Pollution. *Secretary*, L. F. WARRICK, State Sanitary Engineer, State Board of Health, Madison, Wis. (To be presented by title only.)

## PUBLIC HEALTH EDUCATION

*Fourth Session—Small Ball Room*

### PARTICIPATION OF THE MEDICAL PROFESSION IN HEALTH EDUCATION

HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich.

W. W. BAUER, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago, Ill.

W. S. LEATHERS, M.D., School of Medicine, Vanderbilt University, Nashville, Tenn.

RAYMOND H. GREENMAN, Executive Secretary, Tuberculosis and Health Association, Rochester, N. Y.

*Discussion Leader.* IRA V. HISCOCK, Professor of Public Health, Yale University, New Haven, Conn.

## INDUSTRIAL HYGIENE SECTION AND AMERICAN SOCIAL HYGIENE ASSOCIATION

*Joint Session—Sun Room, Washington Hotel*

### SYPHILIS: AN INDUSTRIAL PROBLEM

*Presiding:* C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

Losses and Risks to Industry Attributable to Syphilis. J. R. GARNER, M.D., Chief Surgeon, Atlanta and West Point Railroad Company, the Western Railway of Alabama, Georgia Railroad, Atlanta, Ga.

Should the Treatment of Syphilis Be Included Under the Medical Benefit Arrangement of Industries? C. H. KIBBEY, M.D., Director of Sanitation, Tennessee Coal, Iron and Railroad Company, Fairfield, Ala.

*Thursday, 9:30 A.M.*

# INDUSTRIAL HYGIENE SECTION AND AMERICAN SOCIAL HYGIENE ASSOCIATION (Cont.)

*Joint Session—Sun Room, Washington Hotel*

A General Plan for the Prevention and Treatment of Syphilis in Large Industries. WILLIAM F. SNOW, M.D., General Director, American Social Hygiene Association, New York, N. Y.

*Thursday, 12:15 P.M.*

# PUBLIC HEALTH EDUCATION

*Luncheon Session—Small Ball Room*

Presiding: IAGO GALDSTON, M.D., Director, Medical Information Bureau, Academy of Medicine, New York, N. Y.

Mopping Up. *Informal Discussion.*

*Thursday, 2:30 P.M.*

# FOOD AND NUTRITION

*Third Session—Fairfax Room*

Report of the Committee on Milk and Dairy Products. *Chairman*, WILLIAM B PALMER, Milk Inspection Association of the Oranges, Orange, N. J.

Further Studies on the Growth of *Cl. botulinum* in Defrosted Peas. R. P STRAKA and LAWRENCE H. JAMES, PH.D., Food Research Division, U. S. Bureau of Chemistry and Soils, Washington, D. C.

Report of the Committee on Fruits and Vegetables. *Chairman*, WALTER H EDDY, PH.D., Teachers College, Columbia University, New York, N. Y.

# SYMPOSIUM ON MILKS OF SPECIAL ANTIRACHITIC VALUE THEIR DEVELOPMENT AND USE

Opened by PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

Antirachitic Activation of Milk by Direct Irradiation with Ultra-Violet Rays. GEORGE C. SUPPLEE, PH.D., Director of Research, The Dry Milk Company, Bainbridge, N. Y.

The Addition of Vitamin Concentrates to Milk. THEODORE F. ZUKER, PH.D., Assistant Professor of Pathology, Columbia University, New York, N. Y.

A Preliminary Report upon the Protective Value for Infants of Various Types of Vitamin D Fortified Milk as Compared with Protective and Curative Experiments in Rats. JOHN M. McK. MITCHELL, M.D., JOSEPH STOKES, JR., M.D., DOROTHY V. WHIPPLE, M.D., Pediatric Department, and JOHN EIMAN, M.D., Associate Pathologist, Medical School, University of Pennsylvania, Philadelphia, Pa.

The Rôle of Activated Milks in the Anti-Rickets Campaign. ALFRED F. HESS, M.D., New York, N. Y.

*Thursday, 2:30 P.M.*

## VITAL STATISTICS

### *Fourth Session—Gridiron Room*

Report of the Committee on Proper Allocation of Records. *Chairman*, J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Biometric Studies on United States Army Officers: Somatological Norms in Disease. LOWELL J. REED, PH.D., Department of Biostatistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

*Discussion.* J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

More Uniformity and Reliability in Records. HAROLD B. WOOD, M.D., Epidemiologist, Department of Health, Harrisburg, Pa.

An Original Method of Computing the Probable Approximate Number of Chronic Typhoid Carriers in the State of Maine. WILLIAM L. HOLT, M.D., Director, Division of Communicable Diseases, Department of Health and Welfare, Augusta, Me.

Report of the Committee to Coöperate with the National Safety Council in Preparing Forms for Additional Information Regarding Accidents. *Chairman*, W. THURBER FALES, Sc.D., State Registrar, State Board of Health, Montgomery, Ala.

## CHILD HYGIENE

### *Third Session—Small Ball Room*

#### NEW AND INTERESTING DEVELOPMENTS IN THE CHILD HEALTH FIELD

Estimation of the Effectiveness of Child Health Programs in Ontario by Survey Methods. JOHN T. PHAIR, M.B., D.P.H., Director, Division of Child Hygiene, Provincial Department of Health, Toronto, Ont.

A Report on Handwashing Facilities in Public Schools. SALLY LUCAS JEAN, Health Consultant, New York, N. Y.

A Plan for Promoting More Accurate Records of Infant Hygiene Work. C. A. SARGENT, M.D., Director, Division of Child Hygiene, State Board of Health, Dover, Del.

Practical Parental Education. ROSAMOND PRAEGER, R.N., Supervisor, Child Development and Parental Education, Board of Education, Syracuse, N. Y.

The Part the Laity Plays in a Rural Child Health Program. ELMA ROOD, R.N., Director of Health Education, Children's Fund of Michigan, Detroit, Mich.

The Denver Plan of Parental Education. JESSIE I. LUMMIS, Executive Secretary, Denver Tuberculosis Society, Denver, Colo.

*Announcement.* LOUISE STRACHAN, Director, Child Health Education, National Tuberculosis Association, New York, N. Y.

## INDUSTRIAL HYGIENE

### *Third Session—Cabinet Room*

In Re Silicosis. JACOB GOLDBERG, PH.D., New York Tuberculosis and Health Association, New York, N. Y.

*Thursday, 2:30 P.M.*

## INDUSTRIAL HYGIENE (Cont.)

### *Third Session—Cabinet Room*

**Toxicity of Organic Fluorides.** WILLIAM P. YANT, M.D., U. S. Bureau of Mines, Pittsburgh, Pa.

**Experimental Data in Acute Silicosis.** RALPH POMERANZ, M.D., Radiologist, Tuberculosis Division, Department of Health, Newark, N. J.

**Pathology Attending Asphyxia from Carbon Monoxide and Atmospheres Deficient in Oxygen.** R. R. SAYERS, M.D., U. S. Bureau of Mines, Washington, D. C.

**The Effect of Talc on Workers.** W. C. DREESSEN, M.D., Assistant Surgeon, U. S. Public Health Service, Washington, D. C.

## INSTITUTE ON HEALTH EDUCATION

### Under the Auspices of the Public Health Education Section

The purpose of the Institute is to provide instruction in the content and methodology of Health Education to a limited number of persons actively engaged in Health Education.

Active Health Education workers in official departments of health—state, county and city—and in voluntary agencies are invited to enroll.

Health officers and directors of health organizations are urged to send to the Institute the individuals responsible for Health Education activities in their units.

The registration fee is \$5.00. Write the Association office for enrollment blanks.

*Saturday, October 22, 9.00 A.M.—12.00*

### HEALTH EDUCATION INSTRUMENTS

Discussion of the instruments employed in Health Education; pamphlets, weekly and monthly publications and bulletins, charts, posters, health talks and radio talks; their special utility and their limitations.

*Discussion Leader:* EVART G. ROUTZAHN, Russell Sage Foundation, New York, N. Y.

*Discussers:* BERTRAND BROWN, Director, Division of Publications, Milbank Memorial Fund, New York, N. Y., and W. W. PETER, M.D., Cleanliness Institute, New York, N. Y.

*Saturday, October 22, 2.00 P.M.—5.00 P.M.*

### SOURCES OF INFORMATION

The responsibility of the health educator for the authenticity of his material. How to go about securing dependable information to present on the items selected, to the indicated audiences, and through the preferred mediums. Tapping authoritative sources. The coöperation of the medical profession.

## INSTITUTE ON HEALTH EDUCATION (Cont.)

*Saturday, October 22, 2.00 P.M.—5.00 P.M.*

## SOURCES OF INFORMATION

*Discussion Leader:* IRA V. HISCOCK, Yale University, New Haven, Conn.*Discusser:* CLAIR E. TURNER, DR.P.H., Massachusetts Institute of Technology, Cambridge, Mass.*Sunday, October 23, 9.00 A.M.—12.00*

## BUILDING PROGRAMS

How to formulate a program of Health Education suitable to the community. How to determine the allocation of staff, money and effort. This problem will be considered from the viewpoint of both the official agency, that is, the department of health, and of the voluntary agencies.

*Discussion Leader:* RAYMOND H. PATTERSON, PH.D., Life Conservation Service, John Hancock Mutual Life Insurance Company, Boston, Mass.*Discusser:* IRA V. HISCOCK, Yale University, New Haven, Conn.*Monday, October 24, 9.00 A.M.—12.00*

## PROGRAM EXECUTION

The avenues through which the program might be formulated; the population at large, special groups, schools, primary and secondary, teacher training organizations, work shops and work places, commercial organizations, etc.

*Discussion Leader:* W. W. BAUER, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago, Ill.*Discussers:* GEORGE C. RUHLAND, M.D., Commissioner of Health, Syracuse, N. Y., and EVART G. ROUTZAHN, Russell Sage Foundation, New York, N. Y.

A question period will be arranged for at the end of each discussion though the participants in the Institute will be privileged to interrupt the discussor with pertinent questions.

## MEETINGS OF OTHER ORGANIZATIONS

## AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

All meetings will be held in the Washington Hotel.

Friday A.M., October 21. Joint Session with the International Society of Medical Health Officers.

Friday P.M. Individual Session.

Saturday A.M., October 22. Joint Session with the International Society of Medical Health Officers.

Saturday P.M. Individual Session.

Saturday Evening. Business Meeting.

Sunday-Evening, October 23. Dinner Session. Joint with the International Society of Medical Health Officers.

## AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

Tuesday A.M., October 25. Joint Session with Child Hygiene and Public Health Nursing Sections.

## INTERNATIONAL SOCIETY OF MEDICAL HEALTH OFFICERS

All meetings will be held in the Washington Hotel

Friday A.M., October 21. Joint Session with the American Association of School Physicians.

Saturday A.M., October 22. Joint Session with the American Association of School Physicians.

Sunday Evening, October 23. Dinner Session. Joint with the American Association of School Physicians.

Business Meeting.

## CONFERENCE OF STATE SANITARY ENGINEERS

All day Saturday, October 22, Fairfax Room.

Monday A.M. Individual Session, Fairfax Room.

Monday P.M. Joint Session with the Public Health Engineering Section, Small Ball Room.

Tuesday. Annual Engineers' Stag Dinner Party, Small Ball Room.

## STATE LABORATORY DIRECTORS' CONFERENCE

Sunday, October 23. Luncheon to be followed by an afternoon program of round table discussions of questions pertaining to the administration of state laboratories, Gridiron Room.

(Limited to Directors of State Health Department Laboratories, State Branch Laboratories and their Principal Assistants.)

## ASSOCIATION OF WOMEN IN PUBLIC HEALTH

Monday Evening. Dinner Session, Cabinet Room.

## DELTA OMEGA

Tuesday. Luncheon Session, Gridiron Room.

EXECUTIVE COMMITTEE, HEALTH DIVISION,  
NATIONAL CONFERENCE OF SOCIAL WORK

Thursday. Luncheon Session, Committee Room.

## HEALTH COUNCIL EXECUTIVES

Wednesday. Luncheon Session, Gridiron Room.

## AMERICAN SOCIAL HYGIENE ASSOCIATION

Thursday, Friday and Saturday, October 27, 28, and 29. Social Hygiene Regional Conference.

Thursday P.M. Joint Session with Industrial Hygiene Section, Sun Room, Washington Hotel.

NATIONAL SHELL FISHERIES ASSOCIATION AND OYSTER  
GROWERS AND DEALERS ASSOCIATION OF  
NORTH AMERICA, INC.

Friday and Saturday, October 28 and 29. All day, Fairfax Room.

## Biology

Sex Cycles in Oysters.

Chemical Influences upon Spawning.

Artificial Control of Oyster Reproduction.

## Food and Nutrition of Shellfish

Plankton Foods.

Mineral Requirements.

Vitamin Potencies in Oyster Foods.

Greening and Other Colorations in Oysters from Physiological and Chemical Standpoints.

## Food and Nutritive Values

Human Nutritional Values of Shellfish, Especially Oysters.

Chemical Characteristics of Oyster Tissues with Respect to Carbohydrates (Glycogen), Proteins and Fats.

Mineral Values in Oysters.

Prevention and Correction of Nutritional Anemias.

Iodine in Animal Metabolic Processes and the Value of Iodine in Shellfish.

Vitamins and Other Special Nutritive Values in Shellfish, Especially Oysters, for the Prevention of Food Deficiencies and Protection Against Toxic Food Conditions.

## Food Processes and Packaging

Packaging and Preservative Processing of Shellfish, Including Heat Treatment, Quick Freezing, etc.

## Hygienic Supervision

Sanitation of Industrial Shellfish Activities, Including Field Methods, Laboratory Investigational Procedures.

## LETTER FROM GREAT BRITAIN

THE ROYAL SANITARY INSTITUTE  
HEALTH CONGRESS

THE congress of the Royal Sanitary Institute, the most important of the several health congresses held annually in Great Britain, concluded its deliberations after a full week on Saturday, July 16. The forty-third of the series, the meeting on this occasion was held at Brighton on the invitation of the Mayor and Corporation of the town. From every point of view the congress may be claimed to have scored a success. Certainly it was a most enjoyable meeting, and the considerable amount of work set down to be done was tackled and carried through with the right spirit of cheerfulness and enthusiasm. The total attendance numbered just under 1,400, a figure which, while rather less than that for last year, is rather over the average of recent years.

Among representatives from countries other than Great Britain and the overseas dominions, it was a great pleasure to find a sizeable contingent from the United States of America in the persons of Dr. W. C. Billings, Medical Director at American Consulate General, London; Past Asst. Surgeon F. J. Halpin of the Consulate in Southampton; and Dr. Blanche Sterling of Washington—all of the U. S. Public Health Service; and Dr. Josephine Baker, well known pediatricist. James L. Tighe represented, as he has done before, the Massachusetts State Board of Health; and Professor Winslow filled the dual rôle of representative of the American Public Health Association and Yale University. Professor Sundwall, of the University of Michigan, who, in all innocence, had visited London for the purpose, I imagine, of looking at the School of Hygiene

and such like activities, also found himself making part of the congress and sharing in the work and several of the discussions.

As a humble—and Honorary—Fellow of the American Public Health Association, indeed, it affords me considerable gratification to be in a position to record that members of that body in several spheres made contributions of real moment to the proceedings. At the inaugural meeting, Dr. Billings, acting as spokesman of the representatives from abroad, in a graceful speech voiced congratulation and expressed thanks to the President of the congress (Lord Leconfield, Lord Lieutenant of Sussex and Chairman of the County Council) for his address. Professor Winslow and Professor Sundwall both took part in discussions at the Preventive Medicine and other sections. The former, in addition, delivered what is called “the lecture to the congress,” and by his peroration to an address on “Current Tendencies in American Public Health” evoked an enthusiasm of an intensity definitely astonishing on the part of a people commonly regarded as equally devoid of both enthusiasm and sense of humor.

As the congress met in some twelve sections and conferences, the number of subjects discussed was considerable. Also there was no lack of variety, great thoughts on bed-bugs calling forth opinions no less helpful and profound than those expressed with regard to such problems as the prevention of cancer, the medical treatment of the sick poor, the necessity for birth control, and the advisability of repealing the laws relating to compulsory vaccination. These subjects were dealt with in sections or at conferences in which medical officers of

health particularly were concerned and interested, and some of them proved so attractive—birth control and vaccination, for example—that attendances of round about 400 were secured and even standing room was 'unobtainable. So far as conclusions are concerned, in the case of birth control and vaccination, at any rate, it seemed pretty definite that there was a determination that the time had arrived for doing something about them. Among communications received at the congress it is perhaps worth noting that the message from the Minister of Health was particularly encouraging. His suggestion that the watchword of the congress should be "the efficient maintenance of essential services with a thorough elimination of all unnecessary or wasteful expenditure" was not regarded as foreshadowing anything drastic in the shape of cuts.

#### THE MINISTRY OF HEALTH REPORT

THE report of the Ministry of Health, which made its appearance the other day, is a survey of the whole work of the department. Though it deals fairly fully with purely health questions, for the reason that the Chief Medical Officer (Sir George Newman) himself publishes a separate report, the discussion of this aspect of the Ministry's activities is less complete than it might be.

Sanitary administration, housing and town planning, local finance, administration of the poor law, national health insurance, and contributory pensions, etc., all receive attention, and a vast amount of information, statistical, in respect of expenditure and so on is offered with regard to them. Considerable activity, it is noted, was shown in relation to water supply in rural areas particularly, loans for over £900,000 (five million dollars or so) having been sanctioned.

Unemployment grants are stated to have been especially helpful in stimulating rural schemes. Large expenditures

are shown to have been made in connection with housing and improvement schemes. The actual amount paid by way of government grants in housing subsidies during the year ended March 31, 1932, was over £12,000,000—60 million or so dollars.

The total expenditure on subsidized housing since 1919 is now approximately £630,000,000, representing a figure in dollars I dare not try to calculate or to write down in these days when our, always welcome, American visitors can get a British pound for round about  $3\frac{1}{2}$  dollars.

In regard to poor law, national health insurance and contributory pensions, again a number of striking and interesting figures are given. During the year the average number of persons in receipt of institutional and domiciliary relief amounted to 1,046,079, representing 262 per 10,000 of the population. This is considerably higher than in the previous year, though it is pointed out that the process of appropriating poor law institutions for public health and other purposes has continued to contribute to the reduction in the number of persons receiving relief in poor law institutions.

An interesting test made during the first week of February of this year, to discover the number of persons (in England and Wales) insured under the Unemployment Insurance Acts who received concurrently out-relief and benefit under the Acts, showed the total numbers to be just under 25,000, the dependents numbering 76,329. The insurance payments made during the week totalled over £32,000 and the amount of out-relief £7,853.

In respect of pensions some of the figures given are rather striking: at March 31, 1932, in England and Wales alone the number of beneficiaries receiving widows' pensions amounted to 320,984 widows and 246,112 children, orphans' pensions numbering 13,222. The amount paid during the year was

over 14½ million pounds—70-odd million dollars.

#### MEDICAL BENEFIT UNDER THE INSURANCE ACTS

AS showing the extent and cost of medical service under the Insurance Acts, it is noted that the number of physicians in insurance practice was 14,840; the number of insured persons entitled to medical benefit approximately 15,000,000, and the cost of the benefit over £8,941,000, of which sum the doctors received over £6,467,000, and the insurance chemists for drugs, etc., £1,987,000. No analysis of the conditions encountered and dealt with by the insurance practitioners is given in this report, any references to disease and prevention, indeed, being limited to the part dealing with public health.

Here special consideration is given to tuberculosis and venereal diseases in connection with the descriptions of the progress of treatment and preventive schemes. In respect of venereal disease it is noted that whereas the number of attendances at treatment centers has increased, the number of new cases both of syphilis and gonorrhea is down. The decrease in the former is 4.40 per cent as compared with 1930. In the case of gonorrhea the decrease is approximately 7.47 per cent.

#### THE TUBERCULOSIS CONFERENCE

AS regards tuberculosis the Ministry of Health report notes a definite decrease in the number both of new cases and of deaths in the case of the non-pulmonary form; the actual figures are—deaths 6,160 and cases 18,378. The number of deaths from and cases of pulmonary tuberculosis shows in each instance an increase over that for 1930—54,596 cases as against 54,331, and 29,658 deaths as compared with 29,414. These increases mean probably very little, and certainly called forth no particular comment during the annual

conference of the National Association for the Prevention of Tuberculosis held in London toward the end of July.

Possibly for the reason that the majority of the papers submitted were of a clinical or scientific character, the press secured by the conference was not too good. The nearest approach to sensationalism was made by Dr. Bardswell, an officer of the London County Council and an authority on tuberculosis. Discussing the question of the protection from tuberculosis of the young adult, Dr. Bardswell pointed out that the increase in the death rate from the pulmonary form among young women at ages 15–20 and 20–25 was practically limited to the unmarried. In London he believed waitresses and machinists and others engaged in the poorly paid trades supplied more than their proportionate share of adolescent cases of the disease. In his view, the fact that the young married woman did not break down as did the unmarried worker of the same age was proof of the advantage gained by removal from the ranks of wage earners and the stress of competition.

Another speaker, discussing the recent relative increase of pulmonary tuberculosis in young adults, expressed the view that to a considerable extent it was due to a larger proportion of persons reaching the young adult age without previously having acquired tuberculous infection. Which serves to remind me of the plea of a certain distinguished physician in favor of leaving tuberculous milk alone because he felt that it would be wrong to deprive children of the repeated small doses of tubercle bacilli which served to prepare them for and protect them against the larger doses they were certain to encounter in later life. The fact that there was a real risk of acquiring abdominal or some other form of tuberculosis was, it appeared, not worth worrying about.

PUBLIC HEALTH ADMINISTRATION  
HEALTH DIVIDENDS \*

DAVID LITTLEJOHN, M.D., F.A.P.H.A.  
*Director, Bureau of Rural Sanitation, State Department of Health,  
Charleston, W. Va.*

MONEY which is spent by an individual or a community may be classified either as an expense or an investment. Many individuals and communities have in the past, and unfortunately even at the present time, looked upon money, time, or effort spent in health protection as an expense. This is due to an entirely wrong conception of the object sought and the results attained through the efforts put forth. Money spent for this purpose culminated in many intangible results. In addition we get such results as lowered incidence of sickness and less time lost from work; increased average school attendance due to less sickness; reduction in number of cases and deaths due to communicable diseases; lessening in death rate among infants; and many other similar results.

EXAMPLES OF RETURNS FROM INVESTMENT—PRESTON AND KANAWHA

A concrete example will serve to illustrate the actual money saving resulting from the carrying on of a definite preventive program. In the County of Preston, W. Va., a study and comparison of the incidence of and cost of diphtheria alone, for the 3-year period prior to the organization of a whole-time health service, and for the 9-year period following its organization, gives very startling and definite information regarding the difference in cost to the citizens of the county during these two periods. There was a total saving to the citizens of the county during the past 9 years from the control and prevention of diphtheria alone of \$291,759.03. In other words, from a total investment of

TABLE I  
THREE-YEAR PERIOD PRIOR TO ORGANIZATION OF WHOLE-TIME HEALTH UNIT,  
COUNTY OF PRESTON, W. VA., 1920-1922, INCLUSIVE  
*Total cases of diphtheria reported 226 with 23 deaths*

Analysis of cost of cases and deaths:

226 cases, medical care, average \$50 each.....	\$ 11,300.00
(average 75.3 cases per year)	
23 deaths, average cost of each funeral \$200.....	4,600.00
(average of 7.66 deaths per year)	
23 deaths, average value of each life \$5,000.....	115,000.00
	<hr/>
Total cost for 3 years.....	\$130,900.00
Average cost per year.....	43,333.33

\$54,000 by the county itself during the 9-year period, a return of over 540 per cent was received.

\* *Quart. Bull.*, West Virginia State Dept. of Health, 19, 3 (July), 1932.

TABLE II

NINE-YEAR PERIOD SINCE ORGANIZATION OF WHOLE-TIME COUNTY HEALTH UNIT,  
COUNTY OF PRESTON, W. VA., 1923-1931, INCLUSIVE

*Total cases of diphtheria reported 211, with 7 deaths (average of 23.4 cases  
and 0.77 deaths per year)*

Analysis of cost of cases and deaths:

211 cases, medical care, average \$50 each.....	\$ 10,550.00
7 funerals, average cost of each funeral \$200.....	1,400.00
7 deaths, average value of each life \$5,000.....	35,000.00
<hr/>	
Total cost for 9 years.....	\$ 46,950.00
Average cost per year.....	5,216.00

General summary and comparison:

Average annual cost for period before organization of health unit.....	\$ 43,633.33
Average annual cost for period since organization of health unit.....	5,216.66
<hr/>	
Average annual saving during past 9 years.....	\$ 38,417.67
Average annual cost to county for health unit.....	6,000.00
<hr/>	
Net average annual saving to county.....	\$ 32,417.67

Another similar example comes from Kanawha County, in which a whole-time health service was commenced in 1926. Prior to this time approximately \$8,000 had been spent by the county annually to care for smallpox cases occurring in the county. Since the organization of the county health unit no money has been expended for this purpose other than the small amount involved in the purchase of smallpox vaccine.

These examples represent types of actual saving to the communities in which a definite preventive program is being carried on. Similar illustrations could be duplicated many times over in regard to other ways in which money is saved by this type preventive program.

A few years ago a small city and adjacent community in the northern sec-

tion of West Virginia had quite an epidemic of smallpox. When we visited this community to investigate the conditions and to get the situation under control, the owner of one of the largest stores in the city stated that during the 2 weeks in which the epidemic had already existed, the merchants of the city had lost over \$10,000 a week, due to customers who had gone elsewhere to trade because of fear of contagion from the disease. This latter example illustrates the cost to a community as a consequence of failure to provide for a program of prevention.

The evidence is indisputable that a well organized health service is a paying investment to any community, and should never be considered as simply an expensive luxury, but as an essential and necessary service.

**Organized Medicine and Public Health**—A symposium on the relation of the general practitioner to preventive medicine was held at the annual meeting of the American Medical Association in New Orleans and is reported in the *Journal of the American Medical As-*

*sociation* for June 11, 1932. The authors included G. Gill Richards, Roger I. Lee, Morris Fishbein, and J. N. Baker.

The family physician will always be a most important part in any plan of medical care, whether curative or pre-

ventive in character. Medical participation in health work can do much to extend the influence of preventive services and thus reduce needless sickness and mortality.

#### HEALTH DEPARTMENT REPORTS

Newton, Mass.—The 1931 per capita expense of the board of health amounted to \$.87. Only 1 case of diphtheria was reported in this city of 68,223 population during the year. There were 209 cases of scarlet fever reported, of which 41 per cent were hospitalized. The 123 cases not hospitalized occurred in 95 different homes in which there were 120 other children. There were 4 instances in which secondary cases occurred in the non-hospitalized group as contrasted with no secondary cases among the 164 children who lived in homes from which the cases were hospitalized.

Connecticut—The 1931 annual report of the State Department of Health indicates that the health of the state was particularly good during the year and that certain diseases, including measles, smallpox, diphtheria, and whooping cough, reached a low prevalence. For the third successive year, the typhoid death rate remained below 1.0 per 100,000 population.

Approximately 89 per cent of the population of the state are served by public water supplies, about 24 per cent of the population receive filtered water and 67 per cent receive water that has been protected by chlorination. Summer round-ups carried out in coöperation with the Connecticut Congress of Parents and Teachers resulted in 122 being held, and 2,290 children who were to enter school for the first time were examined as to their physical defects. The state with a population of 1,608,232 has 4,860 registered nurses, besides 1,173 registered outside the state. The public health instruction division re-

cords that over 180,000 persons were reached by exhibits, talks, and film showings besides those reached through 49 radio talks.

Oakland County, Mich.—According to the 1931 annual report of the county health department, 1,235 school children were referred to private physicians for the correction of physical defects discovered by school health examinations. It is also noteworthy that 53 per cent of the school population have been immunized against diphtheria, 9.4 per cent having been given the immunizing doses by their family physician.

The county laboratory made 46,472 examinations during the year at an average cost per examination of \$.17. The public health education service distributed 30,000 baby letters, 6,000 diphtheria immunization letters, and 4,000 each of May Day publications, health examination bulletins, *Child's Bill of Rights*, summer round-up leaflets, besides several thousand other bulletins. A creditable report describes in detail the health services rendered to the residents by this county department.

Quincy, Mass.—A progressive change in the health department organization occurred in 1931 by the establishment of a separate division of vital statistics and the employment of a full-time statistician. It is noteworthy that 97 per cent of the milk supply is pasteurized. There were 46 habit clinics held during the year, with 70 new cases and 93 old cases in attendance. Visits by children, chiefly referred by the school department and by individuals (9 by physicians) numbered 234, while 404 visits were made by the social worker. In the child guidance clinic conducted by the Medfield State Hospital, there were 55 new cases and 20 continued cases. This clinic, held in the Home Making School, was initiated at the request of the board

of public health and the public school authorities. Direct contact is maintained with the school authorities who visit the clinic. There are 10 cooperating agencies.

**Pike County, Ky.**—This annual report for 1931 is dedicated to "The Kentucky Blue Ribbon Children, the nucleus for a higher standard of mental and physical efficiency." There has been nothing found quite equal in value for the instruction of school children concerning the laws of health and hygiene, states the report, to the Blue Ribbon system adopted by the Bureau of Maternal and Child Health of the Kentucky Board of Health.

The requirements call for reasonable norms of growth in height and weight, normal or corrected vision, teeth and tonsils, good posture and health habits, ability to pass the school examinations, vaccination against smallpox, and immunization against diphtheria if under 10 years of age. "What is usually found after these requirements are complied with is a normal, healthy, growing child, with normal physical and mental efficiency. These children are usually more contented, more industrious, more active, have a pleasanter disposition, rarely tardy, and in my observation of the children, I have no knowledge of a case of delinquency."

All of the 215 graded schools of the county were visited during the year in conjunction with an intensive program of health education and study of physical conditions of the children. Records were also made of crippled children during the time of school visits. Of 186 cases recorded, 70 attended the Crippled Children's Clinic which was held under the direction of the Kentucky Crippled Children's Commission. Forty of these cases were recommended for hospital treatment, and most of them are receiving care. This report concludes with a 1-page statistical summary of

major activities and services, with a final page devoted to a map of the area showing the location of schools, roads and principal towns.

**San Luis Obispo County, Calif.**—

One of the most interesting annual reports of the year is the mimeographed record of this county of 39,262. A letter from the health officer to the county board of supervisors gives the purpose and method of preparation of the report, which follows in outline and content the A.P.H.A. *Appraisal Form for Rural Health Work*. A table of contents, an index, together with a map of the state, and a brief description of the county are aids to the reader. The report is a fairly comprehensive health survey of the county, prepared in an interesting and graphic manner. A careful accounting is made of the cost of health services for a period of years and of the sources of revenue.

During the past fiscal year, gross expenditures amounted to \$28,169, but fees from birth and death certificates, sanitary inspections, immunizations, and other sources, reduced the actual cost to \$25,843. Of the tax payers' dollar, a pie chart shows that \$.40 were for education, \$.21 for general government, \$.20 for trust funds and agency transactions, \$.13 for charities and correction, \$.05 for protection of person and property, and \$.01 for public health.

A crude death rate of 8.4 and an infant mortality rate of 57.5 are recorded. During the past 2 years, over 670 children have been given immunization treatment against diphtheria by the health department. The only case of this disease in 1931 was that of a child who arrived in the county a few days before he became ill. A detailed analysis is made of the poliomyelitis problem in 1930 when there were 67 cases. There was only 1 case last year. Eight cases of typhoid fever developed in 1931 with 1 death. The cases were traced to

transients who were in the county when they became sick and infected others before they could be isolated.

Each section of the report first presents standard objectives of service, followed by a frank analysis of accomplishments in the county. Three cities have contracted with the County Board of Supervisors to perform the health work of those cities. In order to carry out this work in an economical manner the county health office is located in the largest city, while one public health nurse resides and holds her office in the next largest city. Various officers of the department visit each of these cities once or twice a week and by telephone communication maintain direct contact in order that prompt service may be rendered when needed.

**Duke Endowment**—The sixth annual report of the hospital section of the Duke Endowment, for 1930, is an impressive record of valuable service in the development of hospital facilities in North and South Carolina. While 6 years ago the private hospitals had 55 per cent of the general beds in North Carolina and 45 per cent in South Carolina, they now have 42 per cent and 28 per cent, respectively, of these beds in the two states. Since 1924, the groups of non-profit hospitals operated by religious organizations and municipalities have increased 1 each in number, and the county group 2, but the group operated by board of trustees for the communities in which they are located has increased 30 in number (from 23 to 53) and 1,700 in bed capacity.

Contributions were made for the care of free patients in 1930 to 103 institutions in the two states. These included

80 general hospitals, 16 tuberculosis sanatoriums, and 7 special hospitals. At the end of the year these hospitals reported 6,300 beds for patients. Of beds available, 58.4 per cent were occupied on the average day, 54.3 per cent in the general hospitals, 79.4 per cent in the tuberculosis sanatoriums, and 71.8 per cent in the special hospitals. The beds for negroes numbered 25.8 per cent of the total. The report contains interesting photographs, building plans, statistical analyses and descriptive text, and is a valuable contribution to the subject of hospital service in small communities and rural areas.

**National Tuberculosis Association**—The 1931 report announces that the death rate from tuberculosis in the United States of 67 is now one-third of what it was when the organization was founded in 1904. "Tuberculosis still takes its greatest toll in the most important years of life, namely, from 15 to 45," and ranks first as the cause of death in this age group, with 1 out of every 5 deaths charged to it. A newly organized publicity department will handle publicity for the Seal Sale and for the Early Diagnosis Campaign, will assist other departments of the association, and will also try to give aid to the publicity work of state and local associations by means of field visits and correspondence. The valuable services rendered in the nursing and industrial fields are noted. "The preventive phase of industrial hygiene has shown marked strides within the past few years and opportunity is given for much health education work through the channels now opened by this newer phase of industrial hygiene."

# LABORATORY A PROJECTION METHOD FOR DEMONSTRATING PARTICLES SUSPENDED IN FLUID

J. A. KASPER, M.D., AND S. L. SIMMONS  
Department of Pathology, Herman Kiefer Hospital  
Department of Health, Detroit, Mich.

It is generally conceded that when any phenomenon is to be demonstrated to an audience, the most practical manner in which to accomplish this is to make that phenomenon apparent to all of the observers at the same time. When particles in suspension are to be demonstrated, there is a difficulty in showing them to large groups at the same time and from the same point of view. Moreover, it is time consuming since it is necessary to give individual demonstrations or, at best, to only small groups. To obviate some of the difficulties, the use of the parallel rays passing through a column of fluid in which particles are suspended to cast a shadow on a screen.

Round tubes are not satisfactory for this purpose on account of the refraction and diffusion of the light. It is necessary to have rectangular chambers so that the rays passing through the fluid are parallel. The rectangular chamber is constructed by placing a thin brass strip,  $\frac{1}{16}$ " thick and  $\frac{1}{8}$ " wide, bent in the shape of the letter "U," between two microscope slides. By means of two screw clamps (used to clamp rubber tubing) applied at the ends of the slides

FIGURE I

FIGURE II

in such a manner as to exert sufficient pressure, the brass strip is held in place. The ends of the strip are bent so that the space between them is  $\frac{1}{2}$ " in width,  $\frac{1}{8}$ " in depth and  $2\frac{1}{4}$ " in height, having a capacity of 0.14 cu. in. or 2.3 c.c. This allows for a border  $\frac{1}{4}$ " wide to the edges of the slides to be filled in with a solid substance such as sealing wax (Figure I). Sealing wax has been found most satisfactory because of its great cohesiveness and its rapidity of solidification. The chamber is shown in Figure II.

A panel is constructed to fit the projection lantern. This panel is placed anterior to the lenses through which the parallel rays from the source of light are transmitted. In the middle of the panel

is a slit  $\frac{1}{2}$ " wide and of the height of the column of fluid through which the rays are to pass. It is so situated that after the rays pass through the fluid in the chamber, they will continue through the center of the magnifying lens at the anterior end of the lantern. To accommodate the chamber and hold it in place in front of the slit in the panel, a slot is constructed into which the chamber can be inserted easily.

This arrangement has proved quite satisfactory for the demonstration of agglutinated bacteria as well as the particles in the Kahn precipitation test. When thrown on the screen, the images are enlarged sufficiently to enable one to determine differences between the sizes of particles in suspension.

**The Purification and Concentration of Diphtheria Toxoid**—This paper reports the results obtained in purifying diphtheria toxoid by precipitation with acetone, at low temperatures. The precipitated toxoid was obtained as a dry powder, readily soluble in aqueous solutions. The powder itself appears to be stable. When dissolved in half the original volume of physiological salt solution, the toxoid remained stable in the cold room for a period of 7 months. Only those toxoids should be used which have been completely detoxified by the treatment with formalin. The formalin is immediately and completely removed by precipitation with acetone.

Filtration through a Mandler filter, or the addition of preservative to the toxoid, did not impair its activities. The flocculating value of the purified toxoid, containing phenol, was lowered considerably by freezing at  $-10^{\circ}$  C.,

while when merthiolate was used as a preservative, it remained unchanged. In refined toxoids diluted to half of the original volume, approximately 62 per cent of the nitrogen was eliminated with about a 15 per cent loss in flocculating value. By this method, the antigenic activity of a toxoid below standard may be increased to a satisfactory standard.

The antigenic activity of the refined product in the immunization of guinea pigs may in general parallel its flocculating value but the relation between the results of these tests may not be proportional nor constant. As an immunizing agent in the guinea pig, the refined product possesses an antigenic activity that is equal to, or greater than, that of the unconcentrated toxoid.—Augustus Wadsworth, James Quigley, and Gretchen R. Sickles. *The Purification and Concentration of Diphtheria Toxoid*, *J. Exper. Med.*, 55:815 (May), 1932.

# VITAL STATISTICS

**Cerebrospinal Meningitis in 1930-1931**—The incidence of cerebrospinal meningitis has undergone some interesting changes in the course of the last few years. After the epidemic outbreak of the war years in Europe and the United States, during which the conditions of infection and of individual resistance were particularly favorable to the disease, the incidence decreased decidedly in most countries of Western Europe, until about 1922 and 1923, when it reached its lowest level. Germany was an exception; here it reached its maximum of 1,622 cases in 1922. Since then a progressive upward movement led to high points in 1929 in Austria, Belgium, Czechoslovakia, Italy, Latvia, Lithuania, Poland, and Yugoslavia. In 1930, no country reached its maximum, while 1931 was the year of highest incidence in England, Scotland and the Netherlands.

During the last 3 or 4 years, England, Egypt, Anglo-Egyptian Sudan, Northern Rhodesia, Macao, Hong-Kong, White Russia, Ukraine, have shown an annual average increase in the neighborhood of 40 per cent; the United States, Scotland, Mexico, and R. S. F. S. R. have shown moderate annual increases ranging from about 20 to 30 per cent; and Canada, Denmark, Germany, France, Switzerland, Austria, and Italy have shown increases which appear to have no definite trend and do not exceed an average of 10 per cent. Sweden, Netherlands, Poland, Hungary, Czechoslovakia, Portugal, Union of South Africa, Algeria, Japan, Shanghai, and Australia have shown decreases.

In England, the incidence of meningitis decreased after the epidemics of 1915 and 1917, with only 30 cases reported in 1923. Since then it has in-

creased, reaching 666 cases in 1930, 2,160 in 1931 and 686 in the first quarter of 1932. The cases of the first quarter of 1932 almost equal those for the first quarter of 1912, when the highest quarterly incidence (742) on record was reported. Apart from the epidemics noted in the army (Aldershot U. D.) meningitis morbidity has been the highest in the West Riding of Yorkshire. In London, where 131 deaths were ascribed to meningococcus meningitis in 1931, the disease attacked children particularly.

In the United States, meningitis prevalence has followed approximately the same course as in England, *i.e.*, decrease after the World War until 1924 and a progressive increase since then. The new maximum, however, was reached in 1929 in the United States. The morbidity had then risen to 9 per 100,000 as against 6.4 and 7.7 for the years 1917 and 1918, respectively.

In the Union of Soviet Socialist Republics the number of reported meningitis cases has been increasing since 1923, a part of the increase being due to the improvement in reporting. Even in towns like Leningrad, only a part of the cases are notified, as shown by the fact that the number of deaths still exceeds the number of cases reported by more than 50 per cent. In this city, from 1926 to 1929, 361 deaths from meningitis as compared with 232 cases were reported.

In Egypt, after brief appearances at the end of 1908 and 1913, the disease took root in 1917 appearing each year in the form of sporadic cases of small local outbreaks. The number of cases remained fairly low until 1929, but since then it has increased rapidly, from 17 cases in 1929 to 99 in 1930 and 871 in

1931. Since the beginning of 1930, isolated cases have been notified in the provinces of Lower Egypt. After the usual summer decrease the number of cases grew rapidly from the end of November, reaching as many as 637 cases per week in the middle of March, 1932. Of the cases identified from November to March, 30 per cent occurred in Cairo alone. Sporadic cases have, in addition, been recognized in all the provinces of Upper Egypt, particularly in Minya, since the end of February.

During recent years, the Anglo-Egyptian Sudan has suffered from cerebrospinal meningitis. Epidemics in February and March, 1932, brought the number of cases, which had fallen to 4 during the last quarter of 1931, up to 418 during the first quarter of 1932. In 1930, the disease prevailed especially in the Province of Mongalla (362 cases), which had for 4 years been by far the most important focus of the disease. It also attacked the Upper Nile Province (147 cases) and the Gedaref district (233 cases).

The 1932 epidemic is spreading in Mongalla Province, Upper Nile Province and the district of Niaro Kau and Funger, in Kordofan. In Funger nearly 200 cases were notified during the week ended March 19.

Sporadic cases occurred from time to time in most of the large ports in the Far East, but their prevalence varied considerably from one port to the other. At Shanghai, the first outbreak in 1920 and 1921 (with 76 and 29 deaths for the 2 years respectively, among the resident population of the International Settlement), was followed by a period of low prevalence. Then in April, 1929, an epidemic broke out which, among the residents alone, caused 403 deaths. At Hong-Kong, the incidence of meningitis was much lower; only 24 cases were recorded there in 1931, 4 of which were imported. The number of cases began to increase at the end of March, 1932,

reaching 31 with 12 deaths during the week ended April 16. Macao, the other port at the mouth of the Canton River, where 3 cases had been recorded in 1930 and none in 1931, has passed through a still more violent epidemic which occurred about a month before that at Hong-Kong. It caused no less than 362 deaths during the months of February, March, and April, a really high figure if it is taken into account that the population of the town of Macao is only about 70,000, and that of the whole territory 160,000.—*Epidemiological Report of the Health Section of the League of Nations* (Mar.-Apr.), 1932, pp. 83-89.

**The Cancer Record for 1931**—The death rate from cancer in American cities was just a shade lower in 1931 than it was in 1930. The death rate from this disease in this and other countries has possibly reached its maximum. The increasing practice of seeking earlier treatment and improvements in surgery and radiology are probably sufficient to arrest a further and substantial increase in the crude death rate. But the situation as it is, cannot be looked upon as otherwise than appalling.

Returns for 50 American cities since 1906 show a rise in the cancer death rate from 71.6 per 100,000 in 1906, to 100.2 in 1920, and 122.3 in 1930. During the last year under review, there was a slight decline to 121.0 per 100,000. A somewhat similar decline took place between 1911 and 1912 when the rate fell from 82.8 per 100,000 in 1911 to 80.3 in 1912. Such declines for short periods are of little practical significance.

An aggregate of 177 American cities shows that during the 2 years 1930 and 1931, the death rate from cancer changed from 117.4 per 100,000 in 1930 to 116.9 in 1931. The rate increased in 82 of these cities and declined in 95, while the range in rate was from a maximum of 215.7 per 100,000 for Madison, Wis., to a minimum of 29.7 for Ham-

tramck, Mich. These rates, of course, are affected profoundly by the admission of non-residents to local hospitals for treatment and do not clearly visualize the exact situation without an extended detailed analysis, which, however, is not possible. Out of 25 cities with cancer death rates in excess of 150 per 100,000 in 1931, 7 cities recorded rates above 170, Madison, Wis. (215.7), Concord, N. H. (195.3), Portland, Me. (194.4), San Francisco, Calif. (190.2), Troy, N. Y. (179.8), Newburgh, N. Y. (172.1), and Oak Park, Ill. (171.9).

The 1931 cancer death rates for the 5 largest cities in the United States are 133.3 for Philadelphia, 192.2 for Los Angeles, 117.6 for New York City, 111.8 for Chicago, and 69.2 for Detroit. It is shown that the actual number of deaths from cancer in these 5 cities increased from 17,326 to 17,680. By way of contrast, attention may be called to the 5 cities, which in 1931 had rates of less than 50 per 100,000. These cities were Hamtramck, Mich. (29.7), Winston-Salem, N. C. (41.6), Cicero, Ill. (47.8), Highland Park, Mich. (49.3), and Flint, Mich. (49.9).

Some of the local changes in the cancer death rates from 1930 to 1931 have been startling. Thus, in Albany, N. Y., the death rate from cancer declined from 173 per 100,000 in 1930 to 147.9 in 1931. The rate for Brockton, Mass., declined from 142.8 to 115.0, and that for Cambridge, Mass., declined from 158.3 to 129.7. A very marked decline occurred also in Holyoke, Mass., from 173.6 to 105.2. The rate for Galveston, Tex., increased from 64.0 to 113.0 and that for Greensboro, N. C., from 62.5 to 128.4. An extraordinary increase occurred in Hartford, Conn., from 99.0 to 145.9. The actual number of deaths from cancer in this city increased from 163 to 244. Another pronounced increase occurred in Hoboken, N. J., where the rate increased from 75.6 to 122.6. In Trenton, N. J., the rate in-

creased from 119.9 to 157.4.—Frederick L. Hoffman, *The Cancer Records for 1931. Spectator*, 128: 10-13 (May 12), 1932.

**Decline of the Birth Rate in France**—A study that has recently been published on the vital statistics of France for 1931, points out that the birth rate fell off sharply toward the close of the year. A comparison of the birth rates for the corresponding quarters of 1930 and 1931 reveals the following differences: first quarter, increase 937; second quarter, decrease 3,537; third quarter, decrease 4,907; fourth quarter, decrease 11,155; for the entire year, decrease 18,662.

The number of marriages furthermore, having diminished by more than 16,000 it is to be feared that the reduction in the number of births may be still greater in 1932.

If one notes that, of the 730,000 births in 1931, 55,000 were of children of foreigners, whereas, of the 680,000 deaths, there were only 30,000 deaths of foreigners, it will be seen that the French excess of births over deaths in 1931 was only 25,000. This small excess runs the risk of being transformed, next year, into a permanent deficit unless something energetic is done to promote a better birth rate. Finally, since the number of emigrants in 1931 exceeded the number of immigrants by more than 25,000, the population of France has in reality diminished, the first time that that has happened since the war.—*J. A. M. A.*, 98: 2150-2151 (June 11), 1932.

**How Prevalent is Syphilis?**—In a recent issue of the *Weekly Bulletin* the number of cases of syphilis in New York City reported directly to the Department of Health was analyzed and the opinion was expressed that the reporting of this disease by physicians, hospitals and clinics was fairly satisfac-

tory. The data presented indicated that approximately 10 per cent of the adult population was infected. Some have thought this figure too high. Confirmation of its essential validity is contained in the Report of the New York State Health Commission which has just come to hand. According to a table in this report, showing the number of cases of syphilis reported in up-state New York 1919-1930, the total number of new cases reported during these 12 years was 145,039, the number rising from approximately 9,000 in 1919 to nearly 14,000 in 1930. In addition to this the results of 1-day censuses of cases under treatment by physicians, hospitals and clinics are shown. From these surveys it can be seen that the number of cases of syphilis under treatment at the time of the census in 1930 was 15,732. These figures, however, do not permit the calculation of an annual attack rate. In this connection the following excerpt from the Commission's report is most interesting:

The State Department of Health, as part of its survey prevalence in 1930, collected information concerning the number of new cases diagnosed for the first time during a 1-month period. If the month (April) for which this information was secured is typical, there is indicated for up-state New York a minimum annual attack rate for syphilis of 4.4 per 1,000 of population, or 25,339 new cases of syphilis annually.

The estimate as to the annual attack rate based on the number of cases presenting themselves for treatment during a particular month checks closely with similar estimates based on the known turnover of clinic patients. For up-state New York, therefore, it is estimated that at present approximately 25,000 cases of syphilis are occurring each year.

If these figures are approximately correct they would indicate that even more than 10 per cent of the adult population is infected with syphilis, for it is necessary to multiply the 25,000 new cases annually by the average number of years of life for these individuals. Assuming an average life span of 40

years for the individual, the total cases of infection would amount to 1,000,000 cases in up-state New York. This is an astounding figure. On the basis of a population of 6 million for up-state New York the figures cited indicate that an assumption of 10 per cent of the population as infected with syphilis would probably not be far from the actual facts, and that to say that 10 per cent of the adults were infected would be conservative.—New York City Dept. of Health, *Weekly Bull.*, 21: 147-148 (May 14), 1932.

**Public Demands Reduction of Road Accidents in Great Britain—**In spite of the new road traffic act, the appalling death toll of the roads continues without sensible diminution. In Great Britain in 1931 no fewer than 6,691 persons were killed and 202,119 injured in street accidents. Every day of the year 18 people were killed and 553 injured. The only favorable feature was that last year the number of fatal accidents was 614 less than in the previous year, but on the other hand the non-fatal accidents were increased by 24,224.

In addition to the figures given for the whole country, the following were given for London: in 1931, 1,325 persons were killed in the streets, as against 1,398 in 1930, a reduction of 5.2 per cent, as against a reduction of 8.5 per cent for the country as a whole. But closer examination revealed the startling fact that decrease of 73 in the London deaths was accounted for almost entirely by the fact that 67 fewer motor cyclists and pillion riders were killed, indicating that the motor cycle was being less used in the metropolitan area. As against the 8.5 per cent decrease in deaths throughout the country must be set the following: (1) There has been a reduction of about 3.2 per cent in the number of vehicles licensed to operate on the roads; (2) the number of per-

sons injured has increased by 13.5 per cent. The returns for London for the first 3 months of 1932 are most disquieting.

The number of persons killed has in-

creased from 289 in the corresponding quarter of last year to 314, and the injured have increased from 9,943 to 10,865.—*J. A. M. A.*, 98: 2,030 (June 4), 1932.

## PUBLIC HEALTH ENGINEERING

### THE TRAVEL OF POLLUTION UNDERGROUND\*

A. F. DAPPERT

*Assistant Engineer, Division of Sanitation, New York State Department of Health, Albany*

ALTHOUGH sewage works operators and superintendents of sewers are probably not accustomed to giving much consideration to the extent to which pollution from structures which are under their control will travel underground, there are occasions when it is desirable to have a speaking acquaintance with the subject. Furthermore, the fact that sewers and sewage treatment plants in general do contribute some pollution to the soil, together with the more significant fact that under certain conditions the consequence of such pollution may be serious, makes it desirable that some attention be given to this subject. It is felt that operators should possess a knowledge of the various points about the plant where soil pollution may occur and the various possibilities, probabilities, and improbabilities.

As an example, at some sewage treatment plants water for general washing and scrubbing purposes is obtained from ground water in the vicinity of the plant. In such a case the operator should have some idea of the safety of such a supply, and to know this, unless he is willing to depend entirely upon

outside advice, he must have some knowledge of whether or not pollution from any of the plant structures is possible. Many other examples could be cited which would indicate the need for the consideration of this subject by the plant operator.

Not infrequently, a neighboring resident will complain that a private well is receiving contamination from either the plant or seepage from the outlet water course, and in such cases it is advantageous to the operator to be so well informed that he can talk convincingly about the matter. In maintaining supervision of public water supplies we are accustomed to place the burden of detecting and eliminating sources of pollution upon the water works superintendent or operator. But usually the water works superintendent will not have the knowledge relative to the peculiarities of the sewerage system that is possessed by the superintendent of sewers. There is therefore an opportunity for the superintendent of sewers to contribute something to the protection of the public water supply. Although it is the responsibility of the water works superintendent or operator to know what possible sources of pollution may be contributed to the water supply, there is need also for the sewer-

\* Paper (revised) presented at the Spring Meeting of the New York State Sewer Works Association, at Buffalo, June 10-11, 1932.

age works operator or superintendent of sewers to know definitely that there is nothing about the sewerage system or treatment works which can be regarded as a source of pollution of the public water supply. It is believed that the sewage works operator should know at all times the definite points at which pollution may be contributed to the soil by the various units of the plant and know also the possible or probable effects of such soil pollution as may be contributed by the various units of the plant.

Among the several points at which pollution of the soil may occur we might enumerate the following:

1. Leaks in sewers which permit the contamination of the immediate surrounding soil with dangerous pollution. Ordinarily from the sewage works operators' standpoint a leak in a sewer is objectionable because of the possibility of admitting large quantities of ground water. However, there are situations occasionally in which the leakage from the sewer into the surrounding soil becomes the major consideration. We need to keep in mind that in municipalities maintaining both sewer and water systems, there is an intricate network of underground pipes which cross and recross each other. In some instances there is need for concern about the sewer which crosses the water main; for example, when due to peculiar hydraulic conditions a negative head may at times exist in the water mains, thus permitting contamination of the water main by leakage from the sewer.

Such a situation arose in one municipality in this state. Sewers and water mains were laid some 35 years ago and for purposes of economy were placed side by side in the same trench. Due to peculiar hydraulic conditions there developed at times a negative head in one section of a water main located in the higher portion of the village. It happened also that a typhoid carrier lived on the street in question, and his place of residence was connected with the sewer that was embedded in the trench along with the water main. Several cases of typhoid fever developed along the street and later investigation disclosed that some of these cases probably arose by reason of the contamination of the water main with sewage from the sewer which paralleled it. It is possible in this case that had the village been served by either a water works superintendent or superintendent of sewers who

fully appreciated the significance of all the various factors involved, improvements would have been made long ago which would have prevented the outbreak.

Another example of the serious conditions that are sometimes created by leaks in sewers is furnished by the experience of a certain city in the middle west some five or six years ago. The city water supply, obtained from a group of wells, was collected in a receiving reservoir across the street from the wells. Water was piped across the street through a tile line which crossed a sewer line 2 feet above it. The sewer became clogged at a point about 400 ft. below the pipe crossing, causing it to become surcharged at its intersection with the water line, and resulting in the serious contamination of the entire city water supply. About 3,000 cases of dysentery developed. The services of an efficient superintendent of water works or of sewers who fully appreciated the dangerousness of the situation might have precluded this trouble.

2. Leaks from plant structures such as wet wells, tanks, etc.—Although generally watertight construction is secured, it is nevertheless possible for leaks to develop. Whether such leaks are serious depends, of course, on local circumstances. Recently the Commissioner of Health felt obligated to refuse to approve the location of two proposed sewage treatment plants because they were too close to the wells serving as a source of water supply for the respective communities.

3. Drainage from sludge beds or intermittent sand filters that seeps into ground strata below the level of the underdrains—I know of one instance where a private well was apparently affected by such seepage.

There has always existed a difference of opinion in regard to the distance to which pollution will travel underground. About 1923, the U. S. Public Health Service undertook a series of elaborate experiments at Fort Caswell, N. C., and some other places to secure authoritative data on the subject. The results are published in *Hygienic Laboratory Bulletin No. 147*. In brief, the Fort Caswell experiments included the construction of shallow pits in sand in which excreta and cow manure and uranin dye were placed. Numerous sterilized wells were then sunk in different directions and at varying distances from the experimental trench,

and frequent samples collected from the various test wells to determine the extent to which underground pollution had progressed. It will probably be of interest to review briefly the condensed conclusions contained in this report.

1. Bacteria pollution as determined by the test for *B. coli* was demonstrated in 1,213 samples of water taken at distances varying from 1 to 232 ft. from the experimental trench.

2. Chemical pollution as determined by the test for uranin dye was demonstrated in the ground water at distances up to 450 ft. from the experimental trench.

3. Both the dye and the *B. coli* travelled only in one direction, namely in the direction of ground water flow.

4. Neither the dye nor *B. coli* was found in other portions of the experimental field.

5. Wet weather resulting in high ground water was found to be conducive to the extension of pollution.

6. Dry weather resulting in low ground water was found to be inhibitive to the extension of pollution, and conducive to the purification of the ground water.

7. The tendency was demonstrated for *B. coli* to localize in the upper blanket at or near the ground water table, and water samples in a given well from this blanket were found to show heavy *B. coli* pollution, while water samples a few inches lower were found to be generally *B. coli* negative.

8. It was found that when the ground water falls, the *B. coli* tend to filter out into the capillary fringe or, in case of a further fall, into the soil and that if the soil remains dry sufficiently long the *B. coli* die out.

9. It was found also that the uranin dye tended to float out in a blanket at or parallel and close to the ground water table, and to filter out upon the fall of the ground water into the capillary fringe and soil, but did not always seem to rise with higher ground water.

10. The investigation demonstrated also that the experimental infection of the ground water remained alive for more than 2 years and 8 months and that uranin dye was recoverable from the ground water for a similar period of time.

11. The investigation brought out also the fact that as pollution travelled it did not appear to expand laterally in a fan shape but on the contrary to contract into a narrow band.

The report brings out admirably the fact that the distance to which pollution can extend depends upon a number of

factors, including rate of ground water flow, the pH of the soil, geological formations, bacterial competition, available food supply, bacterial mortality, rise and fall of the ground water dependent upon the weather, etc.

Where sewage works are constructed on limestone formations or sewers are laid in creviced rock the opportunities for serious contamination of the ground water are much greater than when the structures are built upon sands or clays. There was one instance where a subdivision of a city was to be served by an Imhoff tank with the effluent discharging into a limestone sink hole, situated about 2 miles from the Mississippi River. Fluorescein dye placed in the sink hole appeared in the river about 48 hours after its introduction and about 100 ft. above the water works intake. Naturally the plant was never constructed.

In another case a small village obtained its water supply from deep wells penetrating limestone and located in the high section of the village. The sewage treatment plant was located on the opposite side of the village and in the low section. The effluent from the tank was discharged to a small water course strewn with rock and most of the effluent seeped away. Shortly after the sewage plant was placed in operation the wells developed contamination. An investigation disclosed that the rock strata were inclined at reverse angles to surface slopes and that the effluent from the sewage works was contaminating the wells.

I want to close with a brief recital of an experience recently encountered at Rockville Centre. That village is served by a sewage treatment plant of the activated sludge type and the effluent is discharged onto percolation beds whence it seeps into the ground waters tributary to a small creek. Residences are situated down stream along this creek, and in one particular case the water is used for watering vegetables,

lawns, etc. For some time the residents in the vicinity of the plant complained about the high condition of ground water and the fact that in some private wells the water showed the effects of contamination as reflected by high chloride values.

In April of this year some of the residents along Parsonage Creek below the plant brought an action in the New York Supreme Court, County of Nassau, against the village of Rockville Centre, the principal allegation in which was as follows:

The filter beds are constructed and maintained in such manner that waters therefrom seep into and enter the headwaters of the said Parsonage Creek, carrying with them harmful bacteria and other matters and substances which contaminate and pollute the waters of said Parsonage Creek, rendering them unfit for use and dangerous to the health of the plaintiff and other residents along the course of said Parsonage Creek.

The village officials confronted with a lawsuit of this nature naturally developed a keen interest in the subject of the distance to which pollution will travel underground. Normally the sewage effluent produced at Rockville Centre is discharged onto the surface of one or more of the percolation beds located within the plant grounds, and the effluent then percolates into the natural sand and gravel deposits upon which the beds are constructed, and enters the ground water tributary to Parsonage Creek. There was no reason to deny therefore that seepage from the percolation beds reached Parsonage Creek. It was known also that a sewage effluent produced by the activated sludge process under proper operating conditions is in general terms practically clear, stable, non-putrescible, low in oxygen demand and with a changed and reduced bacteria content so that it may be safely applied to percolation beds or discharged to surface waters without the creation of offensive conditions.

As I have indicated previously there

is considerable literature on the subject which tends to show that polluted waters in travelling a short distance through sand become purified by reason of the natural purification processes established in the soil. In the case of Rockville Centre, then, it could reasonably be expected that whatever bacteria were contained in the effluent as applied to the percolation beds would be completely removed in the first 200 or 300 ft. of travel of the seepage through the soil and that any organic matter contained in the effluent would eventually become completely oxidized. On general principles, considering the distance between the percolation beds and Parsonage Creek (more than 1,400 ft.), it was felt that serious contamination of creek waters could not result from the method of sewage disposal now employed by that village.

It was concluded that whether or not such contamination of creek waters did take place could be demonstrated only by definitely locating the underground path of seepage from the percolation beds between those beds and the creek, and the collection therefrom of samples of water for bacteriological examinations; and that if samples of water collected from the underground seepage from the percolation beds showed no bacterial contamination it was then safe to conclude that harmful bacterial contamination of creek waters does not result from seepage from the beds. This was the general procedure followed during the investigation.

Chlorides, being a harmless inert mineral constituent of sewage, undergoes no change during the process of sewage treatment. The chloride value of the effluent could be expected to be the same as in the original sewage although there is considerable fluctuation in the amount present at different times. In general, chloride would be high in sewage or sewage effluent and low in normal surface or superficial

TABLE I

	Well No.

In 0.1 c.c.....	0+3—	0+3—	0+3—	0+3—	0+3—

ground water. This phenomenon would make it possible to locate with certainty the underground seepage from the percolation beds.

Forty-two borings were made at and in the vicinity of the sewage treatment plant site. Most of these were made with a hand auger to a maximum depth of about 10 ft. In some cases it was not possible to reach ground water with the equipment available, and in other cases ground water was reached a short distance below the surface. Following this method and running an elaborate series of tests for chlorides, the path of underground seepage from the percolation beds was definitely ascertained to be from 50 to 100 ft. wide, although the area of the percolation beds occupied about 6 acres. To obtain samples for chemical and bacteriological analysis, 5 driven wells were sunk into the ground water strata in the line of seepage from beds at varying distances below the beds.

A sample of sewage effluent taken from one of the percolation beds gave among other things the following results (in p.p.m.): Free ammonia 12.5, albuminoid ammonia 0.154, nitrites 0.020, nitrates 0.04, total organic nitrogen 7.14, oxygen consumed 10.0, chlorides 38.0 and *B. coli* present in all of the 0.001 c.c. volumes tested.

Samples collected from the 5 driven wells, tapping the underground path of seepage from the beds gave the results shown in Table I.

Well No. 5 located about 1,400 ft. from the percolation bed tapped the underground stream of seepage about

100 ft. above the point where a spring fed from the seepage issued into Parsonage Creek. The chemical results on this sample are given in Table II.

TABLE II

Determination	p p m
Free Ammonia.....	6.0
Albuminoid Ammonia.....	0.04
Nitrites . . . . .	0.04
Nitrates . . . . .	10.0
Total Organic Nitrogen.....	1.39
Oxygen Consumed.....	1.8
Chlorides . . . . .	38.0

In comparing the results of the chemical analysis of a sample of the sewage effluent with the results for the sample collected from the seepage after passage through 1,400 ft. of sand it will be noted that free ammonia dropped from 12.5 to 6.0 p.p.m.; nitrates increased from 0.04 to 10.0 p.p.m.; total organic nitrogen decreased from 7.14 to 1.39; oxygen consumed decreased from 10.0 to 1.8; and chlorides were practically the same.

The investigation brought out clearly that while seepage from the percolation beds did reach the creek at points about 1,400 and more ft. distant from the percolation beds, and the flow in the creek was composed largely of former seepage from the beds, such seepage as it entered the creek did not contain dangerous contamination as indicated by the results of the bacteriological examinations made upon samples collected from the underground path of seepage. This finding, of course, was in line with prior reasoning. The fact that no *B. coli* and very low bacterial counts were found in

the sample collected from the first well located about 400 ft. below the beds would indicate that all bacterial pollution is strained out in a comparatively short distance of travel through the sand.

The results that occasioned some surprise were the nitrate and free ammonia values of the effluent as applied to the beds and the free ammonia results in the seepage as it entered Parsonage Creek. It was to be expected that the seepage would contain high nitrates, but it was thought also that the effluent from the sewage works would be highly nitrified. As a matter of fact, the sewage effluent was found to be practically devoid of nitrates but high in free ammonia, and the high nitrates in the seepage were due entirely to the nitrification accomplished in the travel of the seepage through the soil.

The fact that high free ammonia prevailed in the seepage at a point 1,400 ft. from the beds brings up an interesting point. It demonstrates at least that chemical pollution can be carried for a long distance through fine sand even when the rate of ground water flow is fairly slow. In this particular case the nitrates were reduced greatly after the seepage issued into the creek and were largely consumed by prolific growths of algae that occurred in the upper reaches of the stream. The free ammonia, however, continued to persist down stream and there was a gradual increase in nitrate values with a corresponding decrease in free ammonia values. The nitrate value of the stream at the point where seepage entered it was 0.5 p.p.m.

and the free ammonia value was over 3 p.p.m., while samples collected from the creek about  $\frac{1}{2}$  mile down stream contained 2.1 p.p.m. nitrates and only 0.14 p.p.m. of free ammonia. The fact that free ammonia was carried in the seepage for a long distance through the soil is therefore regarded as having the effect of increasing the nitrate values in the lower reaches of the stream and consequently contributing to algae production there that would otherwise not have occurred. If no free ammonia had been carried in the seepage it is very probable that high nitrate values would not have prevailed in the creek waters except in the very uppermost reaches of the stream where conditions were exceptionally favorable for algae production and nitrate consumption.

And in this particular case there is some reason to want the nitrate values reduced, as the water enters a pond on the estate of one of the complaining property owners about  $\frac{1}{2}$  mile below the headwaters of the creek.

How far will pollution travel underground? From the Fort Caswell experiments the answer is that bacterial contamination may travel as far as 232 ft. through fine sand and that chemical pollution as indicated by the uranin dye tests may travel as far as 450 ft. From the experience at Rockville Centre the answer is that bacterial contamination will be removed in a relatively short distance of travel through fine sand but that chemical pollution as indicated by free ammonia tests does travel through fine sand for distances considerably in excess of 1,400 ft.

# INDUSTRIAL HYGIENE

## Annual Report of the Chief Inspector of Factories and Workshops for the Year 1931 (Great Britain)—

Topics of special interest to the industrial hygienist include: Explosions, manufacture and use of cellulose lacquers, gassing (especially the description of the deaths of five workmen from anoxemia in a caisson head), the dangerous trades—asbestos, celluloid, cinematograph films, chromium plating, grinding of metals, potteries and refractory materials, and the hygiene of lighting and ventilation. A section on welfare refers to fish-curing, tanning, sugar factories, and cement. A section is devoted to the Home Office Industrial Museum, exhibits, and a conference of directors of foreign industrial museums. Especial interest attaches to the report by Dr. John C. Bridge, Senior Medical Inspector of Factories.

On the whole, the health of women and young persons has been generally satisfactory. The rate of sickness for "nervous disability" shows a tendency to rise. Vastly more days are lost from vague ill-defined disability due to *ennui* than from all the recognized industrial diseases together. This is a pressing problem in industrial health at the present time. No doubt, in the monotonous, repetitive processes of the machine age, the uninterested worker is an industrial invalid.

There was a marked decrease in lead poisoning (168 cases as compared to 265 in the preceding year). Chronic nephritis and cerebral hemorrhage were noted, likewise the confusing of lead poisoning with certain types of acute appendicitis. In potteries, fatal cases were high as compared to non-fatal, but they have been of long standing, not acute. Shot-blasting for removing

(lead) enamel from bath tubs produced cases. In the painting of buildings, dry rubbing down would appear to be the cause of the poisoning (waterproof sandpaper is suggested as the preventive).

Mercurial poisoning occurred in 3 repairers of electric meters, 2 who were using mercury as a catalytic agent and 1 in making thermometers. Five cases of carbon bisulphide poisoning were reported, none serious—4 in the treatment of acetate of cellulose by carbon bisulphide and 1 in the manufacture of the latter.

There were 30 cases under anilin poisoning: Making intermediates (D.N.B., D.N.T., T.N.T.) 10, making or use of anilin 8, making anilin colors, etc., 6, anilin black dyeing 3, 5-chlor-orthotoluidine 1, removing ink stains from linen 1, arseno-benzol process 1. The most frequent cause was absorption through the skin, as following splashing.

One case of chronic benzol poisoning was reported in a man who had worked with the substance for 38 years, and 8 years as superintendent with only slight exposure. The onset of ill-health was sudden. Following extraction of teeth the subject went downhill rapidly and died within a few months. Had there been no exposure to benzol, the diagnosis would probably have been agranulocytic angina. The symptoms noted among a small group of leather dressers were probably due to benzol.

There were 7 cases (2 fatal) due to arseniuretted hydrogen. Six of these (2 fatal) arose in the damping down of dross containing arsenides.

The number of notified cases of anthrax was 21 with 4 deaths as compared with 43 cases and 6 deaths in the previous year. One of the fatal cases was internal anthrax. During the past

32 years there had been reported 315 cases with 69 deaths.

There were 65 cases of chrome ulceration, 41 of which occurred in plating, 8 in dyeing and finishing, 3 in tanning, 2 in the manufacture of bichromate, and 11 in other industries. In one man, ulceration involved the nose, larynx, and vocal cords. Another suffered a severe ulceration of the scrotum due to chromic acid splashed on his apron. The Official Cautionary Chrome Placard should be followed and precautions have not been exaggerated nor made too stringent.

Epitheliomatous ulceration was reported in 156 cases with 46 deaths, compared to 194 with 36 deaths the preceding year. Of those of 1931, 41 occurred in connection with pitch (2 fatal), 35 with tar (13 fatal), 2 with paraffin and 78 with oil (31 fatal). The tar and pitch group showed 29 (2 fatal) in connection with patent fuel works; 15 (1 fatal) with tar distilling; 14 (8 fatal) in gas works; and 18 (4 fatal) in other industries. The oil cases were chiefly in connection with cotton mule spinning, 60 cases (19 fatal). Quarterly periodical medical examinations have now been instituted by the Tar Distillers' Association. The total of recorded cases among cotton mule spinners is now 1,062, including 867 who were still employed when the disease was first recognized, 52 who had retired from 1 to 16 years, and 143 in ex-spinners who had passed into other employment.

Eight cases of carcinoma of the bladder were reported, 5 of whom were employed in the manufacture of synthetic dyes, all coming into contact with *a*- or *b*-naphthylamine (a list is given of other benzene derivatives to which some were exposed).

The 666 reported cases of dermatitis show a decrease (last year, 789). The use of alkaline antiseptic wash (Liq. Chlorinated Soda with boric acid, B.P.C.) has proved its value in connection with oil dermatitis. Ointments

have proved effective in that due to chromic acid, turpentine and its substitutes. Alkalies, especially soda and lime, are the chief causative agents of dermatitis, especially when used as cleansing agents. About  $\frac{1}{3}$  of the reported cases of dermatitis were recurrent.

The Registrar General received 785 certificates of deaths from fibrosis of the lungs. Of these, 319 were silicosis (compared to 241 last year): Pottery 57, sandstone 69 (quarrymen 23, stone masons 46), coal mining 47, grinding 36, gold mining (ex-South African miners) 26, tin mining 17, ore mining 9, other mining 10, refractories (silica brick, etc.) 19, sandblasting 17, steel dressing and cleaning of castings 4, slate quarrying 3, flint and sand crushing 3, granite 1, scouring powders 1. In addition, 9 deaths were attributed to asbestos (with or without tuberculosis). Full particulars are now available of 35 deaths from asbestosis, or asbestosis with tuberculosis. The duration of exposure with these shows half the length of years as in the case of silicosis. Steel shot is gradually replacing sand in abrasive cleaning. Special regulations have been prepared for the asbestos industry (*Form 939*, Feb., 1932, price 1d. net).

Acetone was not demonstrated to be the cause of headache, nose bleed, jaundice, or secondary anemia in various ones among 10 women who complained of the fumes. Two cases of nicotine poisoning occurred from the bursting of a pipe, the hazard being absorption through the skin.

Dr. Horner made an examination of 133 operatives employed from 1 month to 8 years, 26 of whom came in contact with cellulose solutions as brushers, dressers or dippers, and 107 as sprayers of cellulose paint or lacquers. Both males and females were represented. It seems evident that: (1) there is a definite relation between conditions of ventilation and signs or symptoms of ill

health; (2) there is no apparent injury to health where xylol has been the diluent; and (3) local irritation of mucous membranes with headache, depression and fatigue, not amounting to disability, are frequently recorded, especially when ventilation is inadequate. (The report contains much more information.)—Home Department, H. M. Stationery Office, London (Obtainable from British Library of Information, 270 Madison Ave., New York, Cmd. 4098, price 70¢), 1932, 155 pp. E. R. H.

**A Medical Program for 10,000 Employees and Their Families**—Medical service in industry is evaluated in terms of major economics—the ability to recognize value of so-called intangibles, and to convert them into material values—and minor economics which are more readily reduced to a monetary value.

It is possible to have in smaller plants a well designed and effective medical program based on fundamental accepted practice. To operate a medical department successfully in any company requires (1) money, (2) medical personnel, particularly qualified in industrial medicine, (3) a definite objective and program, and (4) the wholehearted support of the executives of the company.

Probably the oldest form of health insurance exists in the mining industry. In many localities it is possible for a married man and his family to obtain complete medical care and hospitalization for the sum of \$40 per year.

In the Consolidation Coal Company the employee contributes directly while the company pays its share of the cost by defraying the expense of the Health and Preventive Medicine Program carried on in the various coal mining communities. There are approximately 10,000 employees who, with their families, compose a population group of from 30,000 to 35,000 persons, scattered over a wide area.

The objective of the program is:

... the treatment and care of sick and injured employees and their families, the application of hygiene, sanitation and education with the objective in view of preventing illness and keeping the employees of our communities in good health.

The personnel of the medical department consists of 22 full-time physicians, 12 public health nurses, several dentists, and a 50-bed accredited hospital. Special arrangements to care for the employee and his family are also made with private hospitals, institutions and consultants. To cover the wide area the organization is divided into medical units, each of which is practically self-sufficient.

Last year 163,024 persons (employees and members of their families) received medical attention. Of these 42,678 were visited in their homes. Some 80–85 per cent of these cases were minor illnesses, for the most part preventable. Experience from these is used for establishing preventive measures.

Every applicant for employment is given a thorough physical inspection, and if accepted, his entire family enters the health régime of the company which includes visits of the public health nurse and doctor, instruction in hygiene and sanitation, promotion of immunization, etc.

Typhoid, smallpox, and diphtheria were quite common several years ago but are now exceedingly rare. Close to 100,000 individual doses of typhoid vaccine and approximately 32,000 smallpox vaccinations were given in the past 3 years.

Strict attention is given to water supply and milk control. A local inspection committee consists of a public health nurse, a physician, and 2 or 3 local health officials who make periodic examinations including all houses, public buildings, stores, restaurants, schools, etc. Considerable improvement has followed this régime. Approximately 350

food handlers have been examined, 10 per cent of whom were found to be carriers of infectious and contagious diseases.

Organized school health supervision is promoted as well as clinics for infants, young children, expectant mothers and for suspected cases of tuberculosis. Other activities concern the development of community groups such as scout, civic, farm women, and church clubs; also fire prevention and dispensing of material relief. Monthly staff meetings are held in the various centers. The plan was inaugurated about 5 years ago.

. . . the amount and character of illness and death varies in direct proportion to the effectiveness of our preventive program. In other words, death, sickness and ill-health decrease as progress is made in prevention.—

D. J. Kindel, Medical Director, The Consolidation Coal Co., Fairmount, W. Va., *Executives Service Bull.*, 10, 7: 7-8 (July), 1932. E. R. H.

**Death of a Leader in Industrial Hygiene:** Sir Thomas M. Legge—Readers of this section should review the obituary by Charles Porter, M.D., in the July issue, 1932, of this JOURNAL (p. 735). Reference is also made to the more extensive memorials in the *Journal of Industrial Hygiene*, June, 1932 (pp. 235-236), and *The Lancet* (London), for May 14, 1932 (pp. 1069-1070), the latter of which carries a portrait of the deceased. A number of the members of our Association will also remember Dr. Legge's visit to some of the eastern states of this country several years ago.

His principal works were *Lead Poisoning and Lead Absorption*, with Sir Kenneth Goadby, his translation into English of Ramboisek's *Industrial Poisons*, his *Shaw lectures*, and *Milroy lectures*. He held the post of Chief Medical Inspector of Factories and Workshops (England and Wales) for nearly 30 years, and died May 7, in the

70th year of his life. The annual reports of his office have been rich sources of information for many years. His loss to industrial hygienists will be as greatly felt in America as in his home country.

He is survived by his widow, two sons and a daughter. E. R. H.

**Mortality Experience of International Typographical Union, 1931—**This mortality experience is presented by Dr. Hoffman in the form of death rates per 100,000. The year 1931 showed a slight advance in the general death rate over the year 1930, and there appeared to be an increase in death rate due to pulmonary tuberculosis, cancer, diabetes, pernicious anemia, pneumonia and hernia. On the other hand there was a decrease in nephritis, cirrhosis of the liver, gastric ulcer and appendicitis. There was a decrease in the death rate due to cerebral hemorrhage, general paralysis, paralysis of the insane and angina pectoris. Other cardiac diseases, embolism and thrombosis showed an increase in the death rate.

The reader is referred to the original article for the statistical tables which cannot be quoted here.—Frederick L. Hoffman, *Month. Labor Rev.*, 34, 6: 1310-1312 (June), 1932. L. G.

**Results of Supplementing the Dietary of Substandard Workers with Cod Liver Oil and Milk—**Sixty-three underweight young women engaged at tasks classified as light muscular activity were provided with a supplement of cod liver oil and milk to their usual home diet. Weekly records of body weight and efficiency rating were made.

Of 45 young women included in a full year's test, the average increase in body weight was 2.6 lb. There was a decrease in absences and an increase in efficiency rating. In a 2-year test all but 3 of 18 young women gained in weight each year, the average gain being

4.5 lb. during the first and 1 lb. during the second year. The average number of absences in a period from December to May showed a reduction of 61 per cent in the 2-year tests. The efficiency increased from an initial of 77.8 per cent to 80.1 per cent for the second year.—W. A. Sawyer and Laura Comstock—*J. Indus. Hyg.*, 14, 6: 207–215 (June), 1932. L. G.

**Decomposition of Dichlorodifluoromethane by Flames**—Dichlorodifluoromethane ( $\text{CCl}_2\text{F}_2$ ), often referred to as F-12 or Kinetic-12 has recently come into use as a refrigerant gas in household refrigerators.

The properties of this gas were studied by the Underwriters' Laboratories and the laboratories of the United States Bureau of Mines, and it was found to be a stable, non-irritating and non-toxic gas by these investigators.

It has, however, been suggested that this gas, when acted upon by flames, may be decomposed with the formation of hydrofluoric acid.

The authors of the present paper by means of a series of computations which are in fair agreement with actual tests conducted by them demonstrated to their satisfaction that no danger can occur due to the leakage of dichlorodifluoromethane subsequently coming in contact with gas flames. The authors conclude that dichlorodifluoromethane does not create a health hazard under these conditions.—Thomas Midgley, Jr., and Albert L. Henne—*J. Indus. & Eng. Chem.*, 24, 6 (June), 1932. L. G.

**Carbon Monoxide Distribution in Relation to the Ventilation of a One-Floor Garage**—This study was designed to determine the concentration of carbon monoxide in a one-story garage in a city in Pennsylvania. The garage studied was 60' x 52' with a ceiling height of 11' 8", it originally possessed no mechanical ventilation, but

windows were provided on three sides of the room. For the purposes of study mechanical ventilation was provided in the form of 6 15" propeller fans located at points on the long sides of the building. Eight surveys were made of the carbon monoxide content of the air of this garage with varying numbers of cars idling. The pyrotannic acid method was used for carbon monoxide determinations.

It was found as a result of this study that upward ventilation yielded the lowest carbon monoxide concentrations in the air, downward ventilation yielded slightly higher results. Cross ventilation and gravity ventilation through the fans and windows occupied an intermediate position, and finally no ventilation and gravity ventilation through fans alone, yielded the highest concentrations of this toxic gas.—F. C. Houghten and Paul McDermott—*Heating, Piping & Air Conditioning*, 4, 7: 495–501 (July), 1932. L. G.

**Medical and Hospital Problems of Workmen's Compensation in New York**—The Governor of the State of New York appointed a Committee charged with the duty of reviewing medical and hospital problems in connection with workmen's compensation insurance. On February 29, 1932, the report of the committee was transmitted to the Legislature by the Governor. The findings of the committee are of great interest and are presented here-with in some detail, since they may be found to be applicable to the functioning of the compensation laws in many other states of the Union.

In connection with hospital problems the committee found that the sums paid to charitable hospitals are in general less than the actual cost to the institutions, and it consequently recommended an amendment to the law providing that charitable or municipal hospitals be entitled to charge the reasonable cost of the services rendered without regard to ward-charity rates established by them.

The committee also recommended a change in the law on authorization of treatment, so that lack of authorization by employers or carriers in cases treated by municipal or charitable hospitals shall not prevent collection of payment for services; the enactment of a lien law in third-party suits similar to that in force in New Jersey; and provisions to insure payment for hospital services in other cases.

In regard to medical problems, the committee recommended the passage of the bill presented to the legislature by the department of labor, extending the scope of the compensation act to cover all occupational diseases. It is contended that the specific schedule, like that existing in New York, does not solve the problem, and as the average cost of covering all diseases in 10 other states is only about 1 per cent of the total compensation cost, the additional cost of the all-inclusive coverage should be only a small fraction of 1 per cent in New York, where 27 occupational diseases are already covered.

The committee suggested that insurance-company doctors be excluded from the room when the claimant is being examined by a state physician, to avoid any suspicion of bias or influence. It also recommended that "lifting" of cases (*i.e.* transfer of patient to other medical or hospital services by means of threat, suggestion or consideration from an insurance carrier) be prohibited under penalty.

The committee found unsatisfactory the practice of having the medical records supplied by agents of insurance companies, and recommended that these records be supplied by a disinterested party. It also suggested a fundamental change in the law, establishing a series of clinics under the supervision and direction of the state.

While present methods are not wholly satisfactory, the committee did not favor the free choice of physicians by patients, but suggested that some method be devised for rating physicians desirous of doing compensation work. It recommended that the subject be referred to the state board of regents.

Increases were recommended in both the professional personnel and the clerical staff of the department, as well as higher salaries for certain members of the latter.

Total disability, in the opinion of the committee, should be interpreted to mean that a man is unable to return to the occupation in which he was engaged when he was injured and should be compensated until he can resume that work. If he earns something at light work in the meantime, that amount should be deducted from the compensation due.

The committee was of the opinion that certain baffling and highly specialized medical problems can best be solved by a group of unbiased experts, and suggested the creation of a supreme court of review on medical questions, drawn from a panel of 75 men and to be used by either party for decisions on a purely medical matter; questions would be submitted to three or five of this body, both sides being bound by the decision.

As to departmental procedure the committee recommend an amendment to the act, relating to appeals; the establishment of a bureau for medical examination of claimants; provision of suitable examination rooms in the different cities or communities, or the use of automotive equipment with adequate facilities; and some changes in the law whereby a man injured while working for an uninsured employer will not become a burden to society because of the failure of his employer to comply with the law.

Bills appended to the committee's report cover the presence of insurance company doctors at examinations, authorization for medical or hospital treatment, reasonable charges by hospitals, and definition of charitable and municipal hospitals.

A special memorandum, endorsed by the majority of the committee, but not by the committee of the whole, expresses disapproval of the practice of insurance companies maintaining and operating clinics.—

(July), 1932. L. G.

**Health Promotion in the Bell Telephone System**—It is the object of the personnel policy of the Bell System to bring out and develop the best quality in each employee and to weld that into effective coöperation in the business. The system comprises 24 operating companies, among them the Western Electric Company, etc. Excluding the Western Electric Company, the Bell Telephone Laboratories and the Bell Telephone Company of Canada, the total number of employees as of December 31, 1930, was 328,956, of whom 203,805 were women and 125,151 were men.

Especial emphasis is placed on the working conditions for women. To carry out the work which they do re-

quires a high type of employee. While tuberculosis or ill defined nervous disorders arise, there is apparently no health hazard from the standpoint of either disease or accident that is characteristic of the telephone industry.

The day is divided into 3 periods of 8 hours each. As a rule at least 1 hour is given for luncheon and rest, and additional rest periods of 15 minutes are allowed mid-forenoon and mid-afternoon. Much attention has been given to adequate seating and proper posture, also to ventilation and temperature regulation and lighting as well as to rest rooms, locker rooms, etc. These conditions are reflected in the homes of the employees. Many of the central offices provide rubbers and umbrellas which may be borrowed in emergencies—a provision of definite value as a preventive measure.

Cafeterias are usually provided and food-handlers are examined periodically. Lessons are given in diet, nutrition and health which have no doubt increased the demand for milk and green vegetables and decreased the consumption of sweets. Many of the companies provide various forms of recreation such as hiking, swimming, and bowling.

Absence from work on account of sickness is divided into two parts: (1) incidental or short-term absence, and (2) absence of more than 7 days. The latter have been recorded and analyzed in a standardized manner since 1913. There is a benefit and medical department. The requirements for physical examinations vary, depending on local conditions and policies but such are emphasized and encouraged, particularly for executives and older employees. Usual medical attention is referred to private physicians.

All general health activities are under the operating department with the co-

operation of the medical department, which latter therefore assumes no direct responsibility.

The voluntary health course has been in operation for 6 years, with approximately 140,000 graduates. Some 3,600 have taken the nutrition course, and more than 75,000 have received a course in safety instruction (chiefly men).—Leverett D. Bristol, *Hygeia*, 10, 5: 438–441, illustrated (May), 1932.

E. R. H.

Annual Report of the Rockefeller Foundation, 1930—The following items of interest to industrial hygienists are found in this volume: Appropriations made during 1930 in connection with the program for industrial hazards and economic stabilization (pp. 220–227) totaled \$980,000, of which \$875,000 were made to Harvard University, Boston; \$50,000 to the President's Conference on Unemployment, Washington, D. C.; \$15,000 to the National Institute of Public Administration, New York City; \$20,000 to the National Institute of Industrial Psychology, London, England; and \$20,000 to the Austrian Institute for Trade Cycle Research, Vienna.

The program at Harvard has now been extended to cover a variety of forms of hazards in industry, including accident and disease. A university committee in which the School of Public Health, the Medical School, the Engineering School, and certain departments of Harvard College, as well as the Business School, are represented, has supervisory charge of the program. The appropriation made by the Foundation in 1930 provided necessary funds over a 7-year period. (See also pages 278 and 284.)—The Rockefeller Foundation, 61 Broadway, New York, N. Y.

## FOOD AND NUTRITION

**The Vitamin D Content of the Fat of Sea Perch, Porpoise and Seal**—The visceral fat of the sea perch (*Sebastes marinus*) and the subcutaneous fat of the porpoise (*Delphinapterus leucas* L.) and the seal (*Erignathus barbatus* M.) were examined both chemically and biologically. The acid value was least in the seal fat (0.91) and highest in the porpoise fat (9.30). The prophylactic method was employed and the experiment lasted for 3 weeks and the degree of rachitogenic effect determined by roentgenograms. By this method 1 gm. of the sea perch fat contained 100 to 150 vitamin D units and that of the porpoise less than 50 units. The fat of the seal was found to contain practically no measurable amount of vitamin D. It was concluded that the content of vitamin D in the intestinal fat of the sea perch was equivalent to the fat of the cod.—S. N. Matzko and D. A. Vital, *Ztschr. f. Unter der Lebens*, 5: 495 (May), 1932.

**The Reducing Power of Vegetable Food Material and Its Relation to Vitamin C; V. The Antiscorbutic Effect of Various Extracts of Cucumber**—Extracts of fresh cucumber were prepared with cold water and with diluted sulphuric acid and these extracts were fed to guinea pigs in varying amounts. At the end of the 63-day experiment, all of the animals, with one exception, on the water extract and the sulphuric acid extract were normal, comparable to the controls receiving 1 c.c. citrus juice daily. In the controls receiving only the basic diet all developed scurvy. The amount of reducing substances present was determined by titration and found to parallel the antiscorbutic potency of the extracts.

The reducing substance in these extracts succumbs to oxidation by atmospheric oxygen more readily than the reducing substance in citrus juice. The investigation of reducing substance in fruit and vegetable material is described (3: 241) by these authors in the same journal.—*Ztschr. f. Unter der Lebens*, 3: 276 (Mar.), 1932.

**A Case of Food Poisoning Apparently Due to Staphylococcus**—Chicken gravy, prepared on Tuesday from left over bits of chicken originally served on the preceding Sunday, when eaten at the evening meal on Wednesday produced violent vomiting, purging and prostration. The chicken when served on Sunday caused no illness.

Laboratory examination of the gravy disclosed no bacteria of the Salmonella group. Large numbers of staphylococcus colonies resembling those of *S. aureus* were found on the plain agar plates.

Sterile filtrates of staphylococcus cultures were prepared and fed to human volunteers. Typical symptoms of gastroenteritis followed. There was close resemblance between the symptoms produced by swallowing small amounts of the filtrate and the symptoms in the persons poisoned by the gravy. In both cases the onset of symptoms occurred 3 hours after the ingestion of the toxic material.—Edwin O. Jordan and John R. Hall, *J. Prev. Med.*, 5: 387 (Sept.), 1931.

**Experimental Study of Possible Routes of Contamination of Cakes with Food-Poisoning Staphylococci**—The object of the present experiments was to determine how cake that had been found to be a carrier of staphylo-

cocci causing food poisoning might have become contaminated—whether the staphylococci might have been present in the ingredients or whether the contamination might have occurred after baking.

Staphylococci introduced experimentally through inoculated egg whites or yolks into various cake batters of either the sponge or butter variety were killed during the baking process. This was true in cakes of pH ranging from 5.0 to 8.2. Staphylococci similarly introduced into a cream filler for cakes were destroyed during the cooking of the filler. Staphylococci inoculated into the filler after its preparation invaded the cake substance. Human feeding experiments showed that both the organisms and the toxic substance were present in the filler and in the cake itself.

It seems likely that in some of the food poisoning outbreaks due to staphylococci in cake, the filler is contaminated after its preparation, the microorganisms from the filler later invading the cake substance.—G. M. Dack, Oram Woolpert, Isabel Noble and Evelyn G. Halliday, *J. Prev. Med.*, 5: 391 (Sept.), 1931.

**The Effect of Heat Storage and Chlorination on the Toxicity of Staphylococcus Filtrates**—Sterile filtrates of staphylococcus cultures known to be capable of producing symptoms of food poisoning were studied to ascertain what effect heating, storage and chlorination had on their toxicity. In several cases ingestion of sterile staphylococcus filtrates, boiled as long as 30 minutes, was followed by nausea, diarrhea and prostration. In other experiments with human volunteers no symptoms followed the ingestion of filtrates boiled for 30 minutes.

Although the toxic substance present in staphylococcus filtrates is not completely destroyed by exposure for 30 minutes to the temperature of boiling

water, some diminution in toxicity may be caused by heating even at temperatures below 100° C. Sterile filtrates stored in the icebox for 3 or 4 weeks did not lose their toxicity.

In one case symptoms of gastroenteritis were produced by a filtrate stored in the icebox for 67 days. While the toxic power of the filtrates does not disappear on storage it is no doubt somewhat weakened.

In testing the effect of chlorine 0.1 c.c. of 0.0915 per cent solution of chlorine was added to a filtrate 3 minutes before it was swallowed. Typical symptoms occurred in 5¼ hours but they were less severe than in the case of the control. When 5 c.c. of the same chlorine solution were added the ensuing symptoms were very slight.

The data show that contact for 3 minutes with a rather strong dose of chlorine did not destroy the toxic quality of the filtrate.—E. O. Jordan, G. M. Dack, and Oram Woolpert, *J. Prev. Med.*, 5: 383 (Sept.), 1931.

**A Preliminary Report on the Bacteriological Examination of Fresh Cream and Artificial (Reconstituted) Cream**—A bacteriological comparison of fresh cream and artificial (reconstituted) cream has been carried out with the following results:

1. The bacterial content of the fresh cream (plate count on standard agar and direct microscopical method) is practically 40 times that of the artificial cream.

2. The average keeping quality of the fresh cream during September to December was 38 hours, as compared with 56 hours for the reconstituted product.

3. The fresh cream reduced double strength methylene blue in two hours. The artificial cream generally took eight hours or over to reduce the dye.

4. The types of fermentation in the two products is very characteristic. All samples of the artificial cream gave a very stormy fermentation within 24 hours at 37° C. The natural product in all cases gave an even non-gassy curd.

5. Anaerobic spore formers of the *Clo-*

*stridium Welchii* group were detected in the artificial cream. These were traced to the milk powder used in manufacture.

—(*Welsh J. Agric.*, 6: 284–9, 1930. Summary taken from Imperial Agric. Res. Conference, 1927. Abstracts of *Papers on Agric. Res. in the United Kingdom*, 1929–30, p. 101.) Abstract, *Bull. Hyg.*, 6: 775 (Oct.), 1931.

**The Distribution of Vitamin B Complex and Its Components in the Peanut**—Two lines of experimentation were followed—one to determine the amount of vitamin B complex in peanuts and the other to determine the proportion of the components (B and G). Virginia Runner peanuts were used, both raw and blanched, the blanching consisting of heating in oil to about 300° F. insufficient to develop a brown color in the kernels.

The peanuts were separated into split halves, hearts, and skins, in the proportion of 95 per cent splits, 2.3 per cent hearts, and 2.7 per cent skins. Rats were fed a B complex free ration consisting of varying percentages of purified casein and starch, meat residue, vegetable fat and salt mixture, supplemented with cod liver oil.

In one series the peanut supplements were added to the basal ration so that all were approximately equal in energy value. On low levels of peanut supplements, the appetite of the rats was affected so that insufficient amounts of the vitamin were consumed.

Another series was run in which definite daily weighed quantities of peanuts were fed to the rats. On a 10 per cent level, none of the peanut products stimulated growth; good growth was made on 20 per cent of raw or blanched splits but not much increase with this level of blanched hearts. Moderate growth resulted with 20 per cent of blanched skins but no improvement when this was increased 50 per cent, possibly due to tannin or other astringent present.

Several months later, these experiments were repeated with the same peanuts but inferior growth showed storage had somewhat depleted the B complex. All of the blanched products contained less vitamin B complex than the corresponding raw products. In the determination of components B and G two rations were used—one devoid of both components and the other containing the antineuritic with very small amounts of vitamin G. The antineuritic vitamin from rice polish extracts did not induce growth in rats on the B complex free ration.

Greater gains were made when autoclaved yeast was substituted, showing peanuts relatively richer in the B than in the G factor.—F. W. Sherwood and J. O. Halverson, *J. Agri. Res.*, 44: 849 (June 1), 1932.

**Increasing the Vitamin D Content of Milk**—Since milk under ordinary conditions is a poor source of vitamin D, numerous trials have been undertaken to increase this vitamin in cow's milk, with conflicting results, except by feeding cod liver oil which tends to depress the fat percentage. In these experiments, irradiated ergosterol was administered, preliminary work having shown that 130,000 Steenbock rat units yielded a marked increase in the vitamin D of the milk from one Jersey cow.

Two Holstein cows in approximately the same stage of lactation and the same milk production were used under winter feeding conditions. The trial was divided into periods of 3 to 4 weeks' duration, and controls were fed 50 c.c. of corn oil, and the experimental animals the same amount of oil, containing in various proportions irradiated ergosterol from 7,500 to 200,000 Steenbock rat units.

The milk was made into butter which was fed to rats and the vitamin D measured by curative and prophylactic methods. The vitamin D content of

the butter fat increased from 0.17 Steenbock rat units per gm. to 2.5 per gm. when 200,000 rat units were administered. Similar results were obtained with chicks as the experimental animals.

Two rachitic babies were fed milk from the cows receiving the 200,000 rat units and showed steady improvement. Post-mortem of the cows used in the

test showed no abnormality from feeding of the ergosterol.

It is pointed out that while it is possible to increase the vitamin D content of milk many times, this method is too expensive to warrant its general application.—W. E. Kraus, R. M. Bethke and C. F. Monroe, Ohio Exper. Sta. *Bimonth. Bull.*, 136 (May-June), 1932.

## CHILD HYGIENE

### CHILD HEALTH TODAY\*

CHILD health today takes into consideration the welfare of the whole child in his varied relationships to home, school, church, and the community at large. Health is a delicate balance which the individual maintains between a number of conflicting forces, some of which reside in the child himself. Others arise from his immediate environment. This health balance is easier to secure in some children than in others. Individual children differ a great deal in their ability to keep healthy. No child is so well conditioned but that some untoward force may upset his health equilibrium. Not only does the child have to make constant adjustments and readjustments but his parents or guardians have to be ever on the alert to protect him.

Scientific knowledge must be applied to child health. Health habits should be inculcated, beginning early in infancy. In many situations the child is helpless to protect himself. For instance, the child has very little if any choice in the selection of his food or in the kind of milk or water he drinks. He has no con-

trol over exposure to communicable diseases in the community. He is at the mercy of motor traffic in the streets and public highways. Over these and many other hazards the enlightened community must exert control through a well organized department of public health. But a health department, no matter how well organized, cannot function effectively without intelligent co-operation on the part of the parents. In a very real sense the public obtains as much health protection as it is willing to pay for. Furthermore, it should abide by the public health regulations. We have at present enough scientific knowledge concerning child health which, if applied more extensively, would give to our children healthier and happier lives. It is especially important at this time that we do not relax efforts to keep our children in the best of condition.

We are on the threshold of a critical period in which more careful scrutiny will be given to programs and methods proposed in the name of child health. Future programs will not be launched upon sentimental propaganda of well meaning but misguided community organizers, but will be formulated on the basis of facts ascertained by trained investigators and carried out by technically trained persons. Practical appli-

---

\* Radio talk over KMTR, Los Angeles, July 6, 1932, by Richard A. Bolt, M.D., Director of the Cleveland Child Health Association and Lecturer in Public Health and Hygiene at the Summer Session of the University of California, at Los Angeles, Calif.

cation of well established principles and methods to the individual child will be demanded of physicians, nurses, dentists, teachers, and social engineers.

There has been recently much loose talk to the effect that our child population has not suffered unduly from the depression. This is very unfortunate as it tends to divert us from the main issues involved in preserving health standards for the child which we have built up after many years of effort. The reduction of infant mortality together with the generally low death rates throughout the country have been pointed to with assurance that we need not worry about the health of our children. While it is true that our infants have been fairly well looked after and that our children in the schools have been kept from actual starvation by supplementary feeding, it by no means indicates that the children are in the best physical and mental condition. Children may be kept alive under such circumstances and at the same time be suffering from malnutrition and other grave disorders. There are indications from certain large centers that a considerable number of children, especially between 2 and 6 years of age, are not in a satisfactory condition at present. It must be borne in mind that the results of malnutrition and undernutrition do not manifest themselves immediately. Furthermore, a chronic state of malnutrition predisposes children to tuberculosis, the effects of which appear but slowly. This was noted distinctly in the war torn countries of Europe following the World War. The effects upon body growth and development may not be evident for many years.

There is another phase of this matter which should receive more earnest attention in these trying years. The uncertainty and insecurity in many of our homes today has a very bad effect upon both the physical and mental life of

children. Mental unrest and defiance of accepted social codes follow closely in the train of broken and upset homes. It is well known that there is a close relationship between physical and mental health. This is already showing itself in all of our large centers of population; in the increase of juvenile delinquency; in the revolt of youth, and in crimes against person and property.

School teachers report that children coming to school without breakfast, or inadequate breakfast, are listless and apathetic. A hungry child cannot be educated properly. Schools have found it imperative to finance extra feedings either from private contributions or out of the public treasury. Some states have passed emergency measures permitting school authorities to use school funds for supplementary feedings. This can be done readily as the school lunch room has become a useful adjunct to every progressive school system.

In the wave of economy now sweeping the country certain cities at first deemed it advisable to close the playgrounds during the summer months. More discerning thought would have determined to keep as many of them open as possible. Public playgrounds not only afford places of recreation for restless and harassed children but also make possible the feeding of those needing special nutritional care. They also afford opportunity to check up on the physical defects of a considerable number of children. This summer in some places physicians, dentists, nurses, and recreation directors are giving excellent coördinated service in the playgrounds kept open at public expense.

Good nutrition is a basic requirement of every child. Fortunately a well balanced dietary for the growing child is not complicated. It can be understood readily by any intelligent mother. The necessary elements which go to make up such a diet are relatively cheap at the

present time. They consist mainly of the following:

1. One quart of clean, wholesome milk for each child daily
2. A moderate amount of green leafy vegetables
3. Fresh fruit, preferably of the citrus variety
4. Some cereal foods. The whole grain products are desirable
5. Butter and fresh eggs

Very little meat will be necessary if the child is given adequate quantities of the foods just mentioned.

California is abundantly blessed with sunshine which is fortunately supplied free to all who will take advantage of it. Children should spend a considerable part of each day in the open air and sunshine and should be allowed ample fresh air during the night. There is absolutely no excuse in this part of the country to allow any child to develop rickets, scurvy, or any other of the deficiency nutritional diseases.

Accidents of one kind or another today cause the death or crippling of too many children. Accidents have assumed alarming proportions among children between 5 and 15 years of age. Accidental deaths of children under 15 years of age make up about one-fifth of the total deaths from accident. Deaths from burns, drowning, falls, and automobile accidents are most frequent. The total number of child deaths from automobile accidents has increased considerably in recent years, although the proportion of child deaths to adult deaths from automobile accidents has decreased almost one-half. While deaths from burns, falls, and drownings have decreased, the automobile death rate remains unduly high. This condition of affairs certainly calls for more vigilance in traffic regulations; more safety education and better provisions for the safety of children in our homes, at the playgrounds, and especially on the streets. Public playgrounds are an anti-

dote against accidents from playing in the streets. Here, as in the case of many other means of prevention, our knowledge far outruns our practice.

A development of major importance in which we are just beginning to get our feet on the ground is that of health education. The immediate future should see a thoroughgoing development of health education, not in name only, but in the basic elements of what actually contributes to health. Pioneer work has already been done along this line, but we must still evolve a sound pedagogical method of health education beginning in parental instruction and running throughout our whole educational system from kindergarten into college. If we can agree upon a few of the fundamentals of health and impress our teachers and prospective teachers with the value of getting these over to the child in the same spirit and with similar methods now employed in the best school practice, much will have been gained for child health.

We now possess two protective measures which should be applied to every child. Vaccination against smallpox and immunization against diphtheria have been thoroughly tested and proved relatively safe and effective against these two diseases. Where they have been applied thoroughly smallpox and diphtheria have gradually disappeared from the community. As young children are most susceptible to these diseases immunization should be carried out early in the child's life.

It is now well known that tuberculosis is usually acquired in childhood either from individuals in the home affected with tuberculosis or from infected milk. We have largely eliminated infected milk by tuberculin testing of cattle and by the efficient pasteurization of milk. As pasteurization of milk becomes more and more prevalent, crippling from tuberculosis of the bones and joints will

become less and less common. Every child should be examined periodically by a competent physician in order to detect the earliest signs of tuberculosis. In this way only can the most effective measures for its control be applied. One of the most serious aspects of tuberculosis today is its appearance in young women of high school and college age. The tuberculosis death rate has been reduced considerably at all age periods except among young women. The dieting fad to secure a slender figure and overactivity at school and in social events undoubtedly contribute to this condition.

The prevention of tuberculosis in childhood is relatively simple if a few principles are carried out as follows:

1. Keep the child away from contact with tuberculous individuals, especially in the early years of life
2. Protect the general milk supply by efficient pasteurization and heat all milk given to young children
3. Maintain a good nutritional status in the child by proper feeding
4. Prevent as far as possible overactivity and fatigue in young people
5. Have the child examined periodically by a competent doctor

We hear much discussion today about the increase of heart disease. The mounting death rate from this disease is giving considerable concern to health authorities. When vital statistics for heart disease are carefully analyzed it is seen that the upward trend in heart death rates during the past 20 years has taken place largely in those over 40 years of age. In every age group under 40 years the death rates from heart disease have decreased. This is particularly encouraging in age groups under 15 years. It is fair to conclude that the efforts put forth for child health have had something to do with this result. Earlier and more exact diagnoses of heart disease are now made. Some of the infectious diseases which are frequently complicated by heart disease

have been brought under better control. Focal infections of the teeth, sinuses, tonsils, and adenoids have received earlier attention. Heart disease in childhood follows closely in the wake of rheumatic fever. This disease also appears to be on the decline in a number of places. The outlook, therefore, for the control of heart disease in childhood is not so gloomy as the crude death rates from this disease would lead us to believe.

Enormous progress has been made in the diagnosis and treatment of diabetes in children. Before the discovery of insulin practically every child who developed diabetes died before reaching 12 years of age. Now, with the proper administration of insulin thousands of children with diabetes at all ages are living and enjoying the normal activities of childhood. Many of these children are exceptionally intelligent. Some of the earlier cases treated with insulin are now married and have had normal children. Summer camps for diabetic children have been established in Cleveland, Detroit, and a few other cities where every facility for diabetic routine is available. These camps should be developed as an integral part of our child conservation program.

Our present-day gains in child health have been along the following lines:

1. Reduction of infant mortality by means of better feeding methods, protection of milk supply, and more skilled medical and nursing care
2. The control of smallpox and diphtheria and certain other communicable diseases
3. Improvement in nutritional standards
4. Prevention and control of tuberculosis
5. Prevention of simple goiter
6. Reduction in certain of the accidents
7. Treatment of diabetes in children

Any retrenchment, therefore, in our public health program which jeopardizes these gains is a confession of our ignorance or callousness to the essential health needs of children.

# PUBLIC HEALTH NURSING\*

**Japan Has a Course for Public Health Nurses**—St. Luke's College of Nursing in Tokyo started a one-year post-graduate course in public health nursing on May 1. Nurses will be prepared for the general field of public health nursing including school and industrial nursing. Instruction in public health nursing, preventive medicine, nutrition, methods of teaching, and social case work, plus practice work in clinic and field, are included in the course.—*Pub. Health Nurs.*, XXIV, 7: 414 (July), 1932.

**Public Health Nursing in Baltimore**—Dr. Joseph W. Mountin, of the U. S. Public Health Service, recently completed a health and hospital survey of Baltimore at the request of the Health Commissioner. Among the 23 major recommendations which he presented as a result of the survey are the 2 following which deal specifically with public health nursing:

No. 18—That as soon as practicable all nursing services of the Health Department be combined into a single generalized service and that a special supervisory staff sufficient to insure proper balance of work by the field nurses be provided.

No. 19—That new appointments to the nursing staff be limited to nurses possessing special training or previous experience in public health work, or that in lieu of such training or experience newly appointed nurses be given an introductory period of training in a special training area.—

**Public Health Is Purchasable, Baltimore** *Health News*, IX, 7: 51 (July), 1932.

**Prenatal Nursing in the Rural Areas**—Health workers have known for some time that wherever there has been

an organized effort to provide adequate maternity care, maternal mortality has been reduced. The report from a Toronto hospital shows that, of 1,020 women who attended a prenatal clinic and were confined in the hospital, only 1 woman died, and she died of heart disease. The Maternity Center records show a maternal death rate of 2.2 as compared with a rate of 6.2 for mothers living in the same district but not receiving their special care.

A great obstetrician has said that prenatal care is not an end in itself but only a means to an end; that good prenatal care is nothing but the foundation of good natal attention; neither is complete in itself, and if either is inadequate both may result in failure. "Nor," he says, "are they complete without good postnatal care. Improper postnatal care may thwart the result of good prenatal care."

In the city or the rural areas every expectant mother needs the assistance of someone who has time to sit down with her unhurriedly and dispel her fears and consider some of the commonplace details of her life. She needs this no matter how adequate her medical supervision. Nursing supervision does not take the place of medical supervision but supplements it.

In rural communities there are greater distances, fewer health workers, and greater social problems; these all complicate the prenatal program. Rural mothers are often lonely and eager for someone to talk to, and an alert sympathetic nurse can do a great deal of constructive teaching if she has the ability to gain the confidence of the mother. One nurse finds that she gets farthest if she takes time to have tea with her patients.

In some districts of Canada prenatal

\* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

group teaching has been done. This has decreased the nurse's travel time, given her more contacts, enabled her to do more effective teaching because demonstrations were possible and exhibits available. In most rural areas, however, this program is not practicable because of distance and lack of transportation, and nurses have to rely on home visits. Some nurses during the long snowy winter months keep in close contact with their patients by mail.

The best publicity for the nurse's prenatal supervision is the service rendered. One nurse increased her number of prenatal cases from 20 to 35 in 3 years. She told her patients if they valued her services to tell their friends about it, which they did.

The success of a rural prenatal nursing service depends upon the coöperation of the public health nurse with the medical profession and her ability to demonstrate the value of such a service to the public.—M. McCuaig, *A Rural Prenatal Programme*, *Canad. Pub. Health J.*, XXIII, 6: 271-274 (June), 1932.

**A Stitch in Time**—A public health nurse in Baltimore brought a sick boy home from school. He had a severe pain in his side and the family's first impulse was to send out and get castor oil to give him. The nurse persisted in entreating them to call the family doctor and persuaded them not to give a purgative, but to apply an ice bag to the side instead. The physician came and within an hour a surgeon had removed the boy's gangrenous appendix. The family physician wrote a letter to the city health department praising the nurse's work.—Public Health Nurse On the Job, *Baltimore Health News*, IX, 7: 53 (July), 1932.

**Public Health Nursing in State Health Departments**—The development of public health nursing in state

health departments is potentially the keynote of a sound public health nursing program in each state. However, in most states the budget and personnel for public health nursing are entirely inadequate to carry on a sound program. The different states show wide variations in the administration and functions of public health nursing in their health departments. A recent study indicates that these services have sprung up haphazardly without any accepted conception on the part of anyone as to the extraordinary opportunities or responsibilities of such services, and with no generally accepted fundamental principles of organization, function, or program.

In every state, also, we find a wide variation in local public health nursing services in organization, personnel, and program. Nationally there are generally accepted principles and standards of public health nursing which cannot be carried out locally to any great degree without some relatively immediate stimulus and leadership.

It is a generally accepted principle that public health nursing functions best as an administrative unit under the direction of a well qualified public health nurse, whether this unit is a separate division or bureau or functions as some part of the general administration set-up.

Local public health nursing organizations have functioned best perhaps where a local group of representative citizens have been associated with them. There might be an advantage in having a public health nursing council consisting of representative citizens from state groups to help strengthen the state public health nursing program.

Here are some functions the state department of public health nursing could carry on:

1. Put into practice standards of local organization and administration, of qualifications of personnel; of content of

program; and of records and statistics.

2. Be of advisory assistance to local nurses and organizations, giving a real educational rather than a mandatory or administrative service.
3. Carry on a staff education program for the nurses in the smaller and more isolated services in particular. This is done in some states by means of group meetings and special institutes. In other states there are field training centers where nurses can go to get "refresher" courses.
4. In some states public health nurses give direct service to local organizations, and this may sometimes be necessary to start the services, but it seems sounder to have local responsibility and local money for public health nursing supplemented by the state.
5. Study general and specific health needs of the state and results obtained from present activities to bring about a better distribution of nursing services in local areas.

If I am right that the sound and effective

development of public health nursing will be furthered most through strong and adequate public health nursing services in state departments of health, it behooves all of us to act accordingly. What does this mean? To my mind, this implies a careful campaign of public education through various local and state groups—nursing, health, medical, and civic. It means backing, supplementing, and co-operating with the services that already exist. The responsibility rests on local public health nursing associations; on state nursing organizations such as S.O.P.H.N.'s and public health nursing sections of state nurses' associations; on the various women's clubs and other civic groups; and on the N.O.P.H.N. It may mean legislation. It is for each state to study what it does mean and to marshal its forces so that what seems to be the most strategic approach to our goals may not be left in its present somewhat chaotic and unrelated condition.—

Katharine Tucker, Relation of State Public Health Nursing Services to County and Local Services, *Pub. Health Nurs.*, XXIV, 7: 357-362 (July), 1932.

# EDUCATION AND PUBLICITY\*

**As Never Before**—This fall and winter, as never before, public health work must prove its case as an essential in community life.

Whether we do more or less in the interpretation of the health agency we cannot do it too well for the safety of the next budget.

Letters on the subject will be welcomed by this department.

**Third and Last Call**—What you have printed or distributed on the following subjects is desired for display at the Washington meeting of the A.P.H.A. in October.

*National and state associations and departments:* requested to send lists of publications, slides, pictures, etc., etc.; copies of plays and other special forms, whatever their subject matter.

*News stories, etc.:* clippings and releases both are welcome, but clippings are especially desirable.

*Any good specimen* of any form on any subject is desired.

*Health councils and chests* are requested to secure material from their member agencies.

*Often two copies* are better than one. All should be addressed to "Washington Display," Evart G. Routzahn, 130 East 22d St., New York.

Some of the topics on which material is especially desired: Cancer, diet and nutrition, diphtheria, heart diseases, measles, mental hygiene, mouth hygiene, rural sanitation, summer warnings and advice, winter warnings and advice.

Depression conditions, house organs or bulletins, popular health education, radio, school health and health education.

**Write Before You Pack**—If you have anything to show at Washington in October, please *write*—and write *now*.

Otherwise, please don't bring exhibits or displays which call for space at Education and Publicity Headquarters.

Last year at Montreal several enthusiastic health workers turned up with material *after all plans had been made and the space allotted*. They were taken care of, but they never knew what other plans were disrupted and disappointments were experienced. *So please write before you pack*.

**The Depression Calls**—To Washington!—The Washington meeting of the A.P.H.A. in October will mean all the more to those who face budget cuts and those who recognize increased need for more and better health education.

**Come Bearing Questions—And Ideas**—We get more and we give more at conventions when we come with specific questions we want answered. Questions to be answered by the speeches or in discussion, in lobby sessions, at exhibitor's booths, or the headquarters of national agencies.

There are cases on record of a staff conference discussing points on which their convention representatives were urged to gather information.

And at least one agency, the Wisconsin Anti-Tuberculosis Association, has discussed what ideas and experiences they could offer as contributions to the discussion in various sessions of a convention.

**Statisticians, Epidemiologists . . .**  
—The displays at Education and Publicity Headquarters at Washington will have something for each of them. Try it once!

---

\* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

**Go To Meetings — Be a "Joiner"**  
—To go to meetings of many kinds—to attend gatherings of all sorts—is a real help to the publicity worker. To meet people and to see people on their own grounds, to learn who they are, what they do, what they are interested in, what they talk about, is a real asset.

To be a member of organizations brings helpful contacts. Every membership held by any staff member of an agency has its value. The payment of a limited number of memberships is a good investment for the agency.

**"Time Out" Needed for Good Publicity**—Health officers and other executives do well to *encourage the taking of time for reading, thinking, studying and planning.*

The urge for production and the doing of many things long have handicapped some of the best workers in health education and publicity. And the pressure for haste and quantity has retarded the growth of the less capable workers.

Whether the worker is skilled or unskilled, time is a prime essential for good and better publicity.

**Rules for Writing Copy**—*Postage and Mailbag* quotes the following rules as having been originated by John H. Patterson, founder of the National Cash Register Company:

- 1 Know your subject
- 2 Use short words
- 3 Write short sentences
- 4 Make paragraphs short
- 5 Use big ideas
- 6 Put only one thought in each sentence
- 7 Write so that a child will understand it
- 8 Say precisely what you mean
- 9 Be brief
- 10 Be logical
- 11 Tell the truth
- 12 Never exaggerate
- 13 Don't imitate
- 14 Be enthusiastic
- 15 Write to impress the reader, not to express yourself or impress a competitor

**Three Billions a Year for Health**—*"We Spend 3 Billions a Year To Get Well, Or to Keep Well,"* says *Business Week*, in the thirteenth of a series of articles on the "American Consumer Market." A diagram, "What the Average American family spent to get well or to keep well in 1929," gives the following estimates: Doctors \$31, Dentists \$12, Home Nurses \$6, Institutions \$39, Appliances \$7, Drugs and Medicines, \$33.

A table shows year by year expenditures, 1919–1930, detailed under general headings: Services; Goods and Appliances; Medicines and Drugs. The \$3,330,000,000 estimate for 1930 was \$446,000,000 drop from the 1929 figures.—*Business Week*, 330 West 42d St., New York, July 20, 1932. 25 cents.

**United Educational Program**—This joint effort under the auspices of the National Social Work Council represents all the fields of health and social work. At present the various sections are concentrating on material for use in the community chest campaigns this fall and winter. The Health Section has already prepared several bulletins of material to be distributed to the chests by the Association of Community Chests and Councils.

Additional data from the field are requested for use in many forms of publicity intended to increase popular understanding of the significance of public health work maintained by public and private agencies.

Because of absence from the country, Dr. H. E. Kleinschmidt resigned as chairman of the Health Section of the United Educational Program, and was succeeded by Paul O. Komora of The National Committee for Mental Hygiene, 450 7th Ave., New York.

**Low Cost Diet**—A "List Of Publications On Low Cost Diet," distributed

by Social Work Publicity Council, 130 E. 22d St., New York. *Copy 4 cents.* This list, given below in full, is submitted for corrections and additions. The aim was to select widely adaptable and easily obtainable material. Some of the titles priced at 1 or 2 cents in quantity are much more attractive and usable in form, and of equal practicability to some of the locally produced cumbersome mimeographed sheets prepared for use by families.

*American Child Health Assn., 450 7th Ave., New York:*

Emergency Nutrition, by Henry C. Sherman. 4 pp. 3 cents; 10 to 24 copies, 1 cent each; lower rates for larger lots.

Food At Low Cost, by Lucy H. Gillet. 4 pp. 3 cents; 10 to 24 copies, 1 cent each; lower rates for larger lots.

*Bureau of Home Economics, U. S. Dept. of Agriculture, Washington:*

Adequate Diets for Families With Limited Income. 16 pp. *Free.*

The Family's Food at Low Cost. 4 pp. *Free.* 100 for 25 cents.

Getting the Most for Your Food Money. 4 pp. *Free.* 50 for 25 cents.

(Send cash orders to Superintendent of Documents, Washington, D. C. Lower rates for larger quantities.)

*Children's Bureau, Washington:*

How to Spend Your Food Money. 1 p. *Free.* 50 for 25 cents.

Emergency Food Relief and Child Health. 10 pp. *Free.* 50 for 50 cents. (Send cash orders to Superintendent of Documents, Washington, D. C. Lower rates for larger lots.)

*New York Nutrition Committee, 105 E. 22d St., New York:*

Feeding the Family at Low Cost. 1 to 19 copies, 5 cents each; 20 to 49, 3 cents each; 50 or more, 2 cents each.

*New York State College of Home Economics, Ithaca:*

Food at Low Cost: References to Pamphlets and Leaflets (annotated—8 titles for untrained homemaker—11 titles for social or health worker). 8 pp. Single copies *free.*

Six low cost menu memoranda (with selected recipes). 42 pp. Single sets *free.*

*Metropolitan Life Insurance Co., New York:*  
Three Meals a Day: Suggestions for Good Food at Low Cost. *Free.*

*President's Organization on Unemployment Relief, 1734 New York Ave., Washington:*  
Food and Nutrition of Our Children. 4 pp. *Free.*

*Evaporated Milk Assn., 203 N. Wabash Ave., Chicago:*

Feeding a Family at Low Cost. 13 pp. *Free.*

*National Dairy Council, 221 N. LaSalle St., Chicago:*

Living Well at Low Cost. 4 pp. *Sample free.*

*Home Economics Committee—Associated Charities, Federal Reserve Bank Bldg., Cleveland:*

A Suggestive Budget for Families of Small Income. 34 pp. 35 cents.

*Council of Social Agencies, 203 N. Wabash Ave., Chicago:*

Chicago Standard Budget for Dependent Families. Includes low cost meals and weekly food lists. Revised June, 1932. 52 pp. 25 cents.

*Family Welfare Association of America, 130 E. 22d St., New York:*

Family Budgets. (List of printed or mimeographed material from 37 cities on family budgets, food budgets, etc.—weekly cash food allowances for family of 5, reported from 21 cities—suggested reading on family budgets, etc.) 14 pp. 6 cents.

"Education and Publicity" department, *American Journal of Public Health, 450 7th Ave., New York:*

Consult files for mention of new publications—and for depression diet discussion references in public health periodicals.

Using Mail in Health and Social Work—Money raising by mail, and the use of letters in promoting an idea will be treated in the Social Service Departmental, Direct Mail Advertising Association, meeting at Hotel Pennsylvania, New York, Oct. 5-7, 1932 (Wednesday through Friday).

The Wednesday morning session will take up: How to Cut Mailing Costs and Solve Postage Problems, Layout of Letterheads and Leaflets, How to Test Mailing and Make the Most of a Direct Mail Budget, How to Build Lists, Standard size envelopes vs. baronial or monarchical size; stamped return envelopes vs. postage saver return envelopes, Typed letters vs. multigraphed; four

line fill in vs. one line fill in, How to Improve the Style of Letters Appealing For Funds. There will be no speeches. Questions will be prepared to be answered by a group of specialists.

The full program and information about the exposition will be sent upon request to D.M.A.A., 19th floor, Hotel Pennsylvania, New York.

#### EDUCATIONAL PUBLICATIONS

Some of the titles listed below will have continued value for reference by the worker in health education.

A single copy of one of them sent to a newspaper editorial writer may prompt an effective editorial. A prominent business man or a leader in the community may welcome a copy of one of the listed titles.

A few copies from this list may bring as significant results as some effort costing much more in money and time.

"Are We Becoming Overly Health Conscious?" by John Sundwall, M.D., University of Michigan, Ann Arbor. Reprint from *Journal of Health and Physical Education*. Oct., 1931.

My answer is emphatically, No. Moreover I am going to try to convince you that the dawn of a much needed era of health consciousness is just appearing on the horizon.

"The Medical Charlatan: Exploiter of the Sick-Well-Ignorant-Credulous"; "The Case Against Prostitution"; "The Truth About Syphilis and Gonorrhea"—three of a series of four 12-page folders well done for reaching leaders in various walks of life. Note the paper, type, lay-out and folds. American Social Hygiene Assn., 450 7th Ave., New York. 5 cents each. Quantity prices.

"Cancer and Its Care: A Handbook

for Nurses," American Society for the Control of Cancer, 25 West 43d St., New York. 47 pp. Free. The bibliography lacks the information as to publishers, paging, and prices to be found in the other recent publication of the society. It is dated.

"Education," Supt. of Documents, Washington. Free. Revised list of government publication. See "Health Education," "Sex Education," "Nurses," etc.

"Annual Medical Service," by Rorem, Julius Rosenwald Fund, 900 S. Holman Ave., Chicago. Free.

"The Costs of Medicines," by Rorem and Fischelis; and "The Healing Cults," by Reed. Committee on the Costs of Medical Care, 910 17th St., N. W., Washington, D. C. Free.

"Free Publications of the Evaporated Milk Assn.," 203 N. Wabash Ave., Chicago. Revised list of publications. Free.

#### ECONOMIES

The careful placing of single copies or small quantities of selected articles, reprints, or pamphlets may win community leaders more effectively than more widespread efforts. More than ever does it seem desirable to win the key men and women of the community. Every month this department tells of publications valuable for this purpose.

"Submitted as an example of money saving" we have received a one-sheet mimeographed condensation of the annual report of the Iowa Tuberculosis Assn., Des Moines.

"Retrenchment—in the spirit of the times it has been deemed wise temporarily to reduce the issues of *Pennsylvania's Health* (State Dept. of Health) to one-half its usual size."

## BOOKS AND REPORTS

**Maternity Handbook**—By the *Maternity Centre Association of New York City*. New York: Putnam, 1932, 178 pp. Price, \$1.00.

Any maternity handbook got out by the Maternity Centre Association is bound to be good: this one with its wealth of detail and of illustration is something which every prospective mother should have. Nurses, too, will find it most useful, more particularly because of the many points of technic brought out. The diction employed is simple, colloquial and clear. Beginning with an introduction, the theme of which is "teamwork by mother, father, doctor, nurse, keeps most mothers well and comfortable," the book goes on to discuss the hygiene of pregnancy, the balanced diet, clothing for mother and baby, hospital and home deliveries, the after-care of mother and baby, and training the baby.

The one jangling note of the book is struck in the preface where the unqualified statement is made that "Barring the few rare and unpreventable accidents, women who have proper care throughout pregnancy, when their babies are being born, and afterwards, do not die." Such a pronouncement, while doubtless cheering to the patient, needs considerable qualification at present to be scientifically accurate.

MERRILL E. CHAMPION

**The Administration of Regulatory Inspectional Services in American Cities**—By *Edna Trull*. New York: *Municipal Administration Service*, 1932, 184 pp. Price, \$1.00.

A mass of materials has been collected portraying the inspectorial services of 38 cities which have been used as a basis for the study. The statistics were

gathered in 1931 and represent the practice of 1930. The cities were selected with a view of obtaining a cross-section in population, in geographical distribution, and in form of government. The report should be of special interest to the health organizations of those cities which participated and no pretense has been made of collecting practise methods from all cities.

It is recognized that there are now many inspectorial services which clutter up and encumber the personnel and finances of health departments which do not have any real health foundation. Not only are most health departments dealing with matters which are distinctly a health menace but they have been forced to give attention to nuisances which are merely offensive to sight or smell and not inherently dangerous.

For the cities in the study much valuable detailed information is presented, affording comparisons in methods, intensity of service, and proportion of personnel to population. There are included several good examples of routine record systems. In fact, this book fills a unique need which has not been previously met and we commend the book to the attention of all public health administrators.

HENRY F. VAUGHAN

**Diet and Weight Control**—By *Shirley W. Wynne, M.D.* New York: *Liveright*, 1932. 223 pp. Price, \$1.00.

This volume is evidently written to meet the need of that vast majority of the population who are able to read but incapable of any more complex mental process. This group, or should one say horde, constitute the mystics who believe in bath salts, rolling pins, etc., as

a means to promoting health and the fashionable figure. Evidently Dr. Wynne has the woman in direct focus since he uses 150 lb. as example of obesity in a person whose ideal might be 120 lb.

The book includes both a regimen for losing fat and also for gaining it. The lower diets for reduction are on a 1,300 calory basis. Many fat persons do not begin to lose until the diet is below 1,000 calories daily.

The general treatment of the scientific aspect of nutrition is as clearly stated as possible in a book of this kind. The method recommended, while not new in principle, is given in sufficient detail so that no excuse for infractions of diet is possible. The person who contemplates a diet regimen is amply warned that new habits must be formed; in effect that the regimen is a life sentence. Indeed, the writing of this sort of book is sufficient evidence of incurable optimism; a number of clinics have recently reported the results of "follow up" studies on obesity patients and these indicate that only a small percentage of patients successfully "reduced" had not regained the lost pounds in 2 years. The common reason seems to be lack of self control—not a rare human trait.

One feature of the volume merits note: Wynne brands some of the much advertised "cures" for what they are—brazen frauds. One could wish he had been more emphatic since his position carries authority. The money mulcted from the people in this business spells dividends even in depression.

NELLIS B. FOSTER

**Prevention of Disease in Childhood**  
—By Paul L. Parrish, M.D., F.A.C.P.  
New York: O. E. Saunders & Sons,  
1931. 89 pp. Price, \$1.00.

This is a small book written, so the preface says, for the guidance of young or inexperienced mothers and the emphasis is evidently intended to be

placed on prevention. This makes it of especial interest to public health workers and gives the latter the right to judge its statements in the light of public health knowledge of the present day.

Some features of the book are very good: it has a complete table of contents and the reading matter is well broken up by the use of headings. Also it is brief and mostly, though not entirely, free from technical terms.

When we come to the public health aspects, however, several criticisms may justly be made. For instance, the subject of immunization is treated without any mention being made of toxoid as an alternative to toxin-antitoxin. Milk is discussed as if the only information available were that of several decades ago. If the writer ever had been a health officer he would not have made the ingenuous statement, "in a country such as this, where good, pure raw milk can be obtained, it (that is, pasteurized milk) has little place in infant feeding." Pasteurization is said to consist "in heating the milk to 160° for 20 minutes" and to make matters worse, even this temperature, according to the author "does not kill tubercle bacilli." Over-emphasis is placed on the destruction of vitamins by heat. Grade B milk is referred to as if it were the only alternative to certified milk.

Since other manuals are available, as simple and more accurate, one's choice would not fall on this one.

MERRILL E. CHAMPION

**Medical Entomology.** A survey of insects and allied forms which affect the health of man and animals—By William A. Riley and Oskar A. Johannsen. New York: McGraw-Hill. 476 pp. 184 figs. in text, 1932. Price, \$4.50.

This is an entirely rewritten edition of the authors' *Handbook of Entomology*, published in 1915. Instead of dividing the subjects into the general

topics of poisonous, parasitic, and vector insects, the authors have treated the insects and related animals in their systematic groups, though not in the usual systematic order.

The early and later history of the relations of arthropods to disease is briefly reviewed in the opening chapter. This is followed by a discussion of the ways in which arthropods affect health. The arachnids come first in the systematic discussion, including the poisonous "black widow" spider, solpugids, scorpions, chiggers, itch and hair follicle mites, and the ticks, especially the carriers of Texas fever, Rocky Mountain spotted fever, tularemia, Oroya and relapsing fevers.

The insects proper are then taken up in the accepted sequence, beginning with body, head, and pubic lice in relation to typhus and trench fever. This is followed by a discussion of the true bugs, or *Hemiptera*, including the bed bug and the assassin bugs, especially the carrier of Chagas' disease. The beetles (*Coleoptera*) are concerned only to a very limited degree as facultative parasites, as vectors, or as poisonous species, and *Lepidoptera* mainly as the source of irritating or poisonous scales or hairs. The *Diptera* play a much larger part, the sand flies (*phlebotomus*) being implicated in 3-day fever, Oroya fever, verruga peruviana, Carrion's disease, and more recently in the Leishmanioses, kala azar, and oriental sore; the mosquitoes in malaria, filariasis, yellow and dengue fevers; and flies in typhoid, and various myiasis; and fleas in plague.

The book is a mine of carefully selected, well organized, and clearly stated information about insects in relation to disease, control and preventive measures, and the essential biological facts pertaining to understanding these relations. Keys for determination of important species are included and an extensive bibliography and index are provided. It is an invaluable text book and a very

useful work of reference for the public health worker and for the laboratory.

C. A. KOFOID

**An Introduction to Materia Medica, Drugs and Solutions—By Stella Goostray.** (3d ed.) New York: Macmillan, 1931. 214 pp. Price, \$1.75.

The third edition of Miss Goostray's *Introduction to Materia Medica, Drugs and Solutions* (September, 1931), makes a very helpful book for the young teacher. The subject matter has been rearranged somewhat, to give the student a more interesting approach. The sequence is logical and the content adequate for an elementary course in materia medica.

Interesting references, suggested exercises, and blank pages for the use of the student, add to the practical value. It is small enough to be carried about by the private duty nurse, a point also in its favor, making a rather comprehensive review of commonly used drugs, their dosage and action. "Multum in parvo," we would say of this little book.

HANNAH STEVENS.

**The Science of Human Living—By Mae Johnson Corwin and Walling Corwin.** San Francisco: Harr Wagner Publishing Co., 1931. 464 pp. Price, \$1.68.

The authors have added another excellent volume to their science series. This book has been prepared for junior high school students and it is written in an interesting and flowing style. It is a text that combines physiological facts and health education. It vitalizes technical physiological knowledge by showing how it can be put to practical use in daily healthful living. The book covers a wide field, including sections on personal hygiene, public health, approved health habits, mental health, home sanitation, infant welfare, and home nursing.

The student is introduced to personalities who by perseverance and right living have developed strong, healthful bodies and to men and women who have contributed to the science and promotion of public health.

Diagrammatic illustrations, specific examples illustrating the subjects discussed, and enough statistics to be impressive yet not burdensome add to the value of the text. A lesson plan is incorporated in each chapter and the comprehensive index and bibliography will be aids to the teacher and pupil.

This book should enrich the well-being of every boy and girl who reads it.

A. B. TOWSE

**Elementary Bacteriology**—By *Joseph E. Graves, Ph.D., and Ethelyn O. Graves, M.D.* 2d ed. Philadelphia: Saunders, 1932. 535 pp. 130 ill. Price, \$3.50.

The changes and additions in this second edition have necessitated a slight increase in the number of pages, but the original plan of the book has been preserved. The chief additions are in the sections dealing with milk, butter, water, the bacteriophage, and the application of bacteriology to arts and industries. Some new and good illustrations have been added. The fundamentals of bacteriology are presented in a full and interesting manner which should hold the student's interest. The historical treatment of various phases of the subject are particularly to be commended. The make-up and printing of the book are excellent.

FRED O. ADAMS

**Public Health Organization**—*Report of the Committee on Public Health Organization. A Publication of the White House Conference.* New York: Century. 338 pp. Price, \$3.00.

This report includes, in addition to an introductory statement, sections on rural, city, state, federal, and non-official public health organization, to-

gether with chapters on the Training of Personnel, the Administration of Child Health Work as Part of Official Health Programs, Relation of Practitioners of Medicine and Dentistry to Health Programs, Health Aspects of Food Control, Research, and a final chapter of Recommendations.

Each section contains a summary of findings and conclusions, a somewhat detailed discussion of types of organization and service, and the extent to which various types of organizations and services are carried on. For those desiring even more specific detailed information, there are numerous tables giving the states, counties and municipalities carrying on various types of service; increases or decreases in such services in recent years; and per capita expenditures and salaries of some of the more important administrative positions. The data covered are for the year 1929. For the most part, the years 1923 to 1929 are included, although in some instances information is available from 1915 to 1929.

Among the many important conclusions are:

Rural health departments should be based upon the county unit, and should be an integral part of the county government. For counties where the population is too small, or the financial resources inadequate to justify a separate organization, some plan of uniting with other counties to form a larger health district should be devised.

The system of state and federal subsidies to promote and maintain county health departments has proved its utility and should be extended.

There should be better coördination in the expansion of consultant service to local health departments, and state and federal public health services should play a leading part in the performance of such service.

Some activities now included in the program of most health departments can be transferred gradually to the general practitioner of medicine. In the interest of child health, in so far as practical, the family physician should become a practitioner of preventive as well as curative medicine.

The experience of the municipal departments

has demonstrated conclusively that programs for the improvement of the health of the mother and child can be conducted successfully only as part of the general program of a well organized health department.

The health officer of any governmental unit must be recognized as the one person directly responsible for the health of the people in his district. . . . It is the primary duty of the nonofficial agency to support and aid him in his difficult task.

The nonofficial agencies in a given community should join together in a health council, preferably under the chairmanship of the health officer or his representative. They should make a serious study of their common problems and relationships and reach definite agreements as to the sphere of each.

These are but samples of the many important conclusions of the committee. Every person interested in public health organization and administration, particularly every health officer, will find this publication a most important reference book. CARL E. BUCK

**Social Work Administration—***By Elwood Street. New York: Harper, 1931. 466 pp. Price, \$3.00.*

The principles underlying successful social work administration are discussed in a comprehensive manner in this book which is one of the Harper's Social Science Series. The book deals with a wide range of subjects, including administration, organization committee management, the choice and equipment of an office, the selection of personnel and policies, budget making and control, statistics in administration, and team work between agencies. Organization charts and other graphic methods are illustrated. This volume should prove useful as a guide to administrators of social agencies and of other types of organizations. The observations and experiences may be adapted to local needs and opportunities. IRA V. HISCOCK

**The Insect Menace—***By L. O. Howard. New York: Century, 1931. 374 pp., 64 ill. Price, \$3.50.*

This volume was written for the pur-

pose of arousing the public to an appreciation of the insect menace. With this in mind, the author has presented his appeal in nontechnical language, and has used numerous examples, derived from the literature as well as his own observations, to illustrate his conception of the insect menace to man. It is a very interesting account of the ravages of insects, of the development of methods of biological, mechanical, and chemical control.

The author points out that insects have been in existence some 40 million years or more as compared with about 400,000 for man. Since the generation time of insects is so much shorter than that of man, insects have had 12,500 times the opportunity to develop forms suitable for their preservation. Other advantages of insects, such as the superiority of their anatomical structure, size, protective coloration, rate and types of reproduction, and more rapid digestion of food, are described. The one possible advantage of man over insects, he states, is in the nervous system.

As interesting examples of specialization of aquatic insects, the author speaks of the dragon fly as an "animated fly trap," and calls a species of water bug an "animated baby carriage."

The multiplication of a number of serious insect pests, such as the European corn borer, the clover-seed midge, and the cotton boll-weevil, is attributed to the agricultural methods being employed. These and other pests have increased because man has made more food available. The monetary loss during 1920 in the United States from insects has been estimated at more than \$2,200,000,000, which does not include the losses resulting from diseases of man transmitted by insects, which cannot be estimated with accuracy. Such diseases as malaria and yellow fever result in enormous labor losses and sometimes loss of commerce.

In order to combat the depredations of insects, studies are being made of their life histories to determine what variations in cropping methods will tend to decrease the chances of insects increasing in numbers. Other studies are being made to find and utilize secondary parasites for control. The narrative telling of the introduction and rearing of insect parasites to prey upon other insects is very interesting. These and other studies have already provided some measures for the control of important insect pests.

The author suggests that if the wastes caused by insects could be prevented, there would be no need for birth control measures to prevent an over-population of the world. An abundance of anecdotes and illustrations serves to prevent the reader from becoming depressed by realization of the seriousness of the insect menace.

The standing of the author assures the substantial accuracy of the statements in the book. It can be recommended to all readers, professional or otherwise, without hesitation.

NEWELL R. ZIEGLER

*Problems of City Life*—By Maurice R. Davie. New York: Wiley, 1932. 732 pp. Price, \$4.25.

This volume represents an intensive study of modern city life, from the viewpoint of urban sociology. It emphasizes normal conditions in dealing with both physical and human environment. The book is divided into 5 parts of 3 to 6 chapters each. Following a consideration of the modern social en-

vironment, the growth of cities, city planning, the traffic problem, and housing, in Part III 6 chapters are devoted to an understanding discussion of health. Parts IV and V, respectively, deal with Education and Recreation.

The author has succeeded in presenting the subject of health in relation to other sociological factors in a well balanced, forceful manner. Health workers who are considering their relationship to other community activities, and persons who are engaged in educational and recreational activities, as well as students of sociology, will find this an interesting and valuable reference.

IRA V. HISCOCK

*A Child's Book of the Teeth*—By Harrison Wader Ferguson, D.D.S. Yonkers, N. Y.: World Book Company, 1932. 106 pp. Price, \$.68.

This is a revised and enlarged edition of a charming little book which ought to interest parents and teachers as well as children. The illustrations, which are by the author himself, are amusing and clever as well as instructive. Adequate emphasis seems to be given to diet in its relationship to teeth and at the same time the subject of cleanliness is not overlooked. The toothbrush drill is retained, though not perhaps in its pristine glory. A good deal of ritualistic hokum that used to attach to this device, though presumably it has some teaching value.

The book can be heartily recommended to all who are concerned with teaching dental hygiene to children.

MERRILL E. CHAMPION

## A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

**Heart Disease**—"In New York City, for the population as a whole, there is no evidence of any increase in the real death rate from heart disease." Let the viewers-with-alarm take note.

BOLDUAN, C. F., and BOLDUAN, N. W. Is the "Appalling Increase" in Heart Disease Real? *J. Prev. Med.*, 6, 4:321 (July), 1932.

**Finding Tuberculosis Early**—Modern tuberculosis case-finding calls for tuberculin testing all children and X-raying the reactors; where X-rays are suspicious a complete physical examination is indicated. So concludes this excellent Detroit study.

BRACHMAN, D. S. Modern Case-Finding in Tuberculosis. *Am. Rev. Tuberc.*, 26, 1:89 (July), 1932.

**Physical Impairments and Longevity**—Included in this important study are a list of physical impairments found in "well" adults, defects considered not sufficiently serious to exclude the victims from life insurance but which did result in excess mortality.

BRITTEN, R. H. The Physical Impairments of Adult Life; Association with Subsequent Rates of Mortality. *J. Prev. Med.*, 6, 4:249 (July), 1932.

**Measures of Health**—The conclusions of this critical summary of medical examination records—that statistics derived from health examinations are valueless as *absolute* measures of health but are of incalculable value in their *relative* comparisons—make the paper one which every health worker should take to heart.

BRITTEN, R. H., and GODDARD, J. C. A New Measure of the People's Health. *Milbank Quart. Bull.*, 10, 3:223 (July), 1932.

**Smallpox Mild and Severe**—No evidence can be found to indicate that mild smallpox has ever reverted to the

classical type. The many outbreaks of the severe form probably are due to importations. These conclusions may well be remembered by vaccination propagandists who will still have plenty of ammunition.

CHAPIN, C. V., and SMITH, J. Permanency of the Mild Type of Smallpox. *J. Prev. Med.*, 6, 4:273 (July), 1932.

**Endemic Typhus**—Evidence pointing to the rat flea as the common vector of endemic typhus from rat to rat and rat to man is summarized. It is suggested that epidemics of louse-borne typhus may have their origin from infection transmitted from rat to man by fleas.

DYER, R. E., *et al.* Endemic Typhus Fever in the United States. *J. Infect. Dis.*, 51, 1:137 (July-Aug.), 1932.

**Smallpox in Fitchburg**—Only 3 of 60 cases of smallpox occurring in the Fitchburg (Mass.) epidemic had been vaccinated before exposure and none of these had been vaccinated within 45 years. Yet the antivaccinists (from other towns who weren't exposed) raged as usual.

FEEMSTER, R. F., *et al.* The Recent Smallpox Outbreak in Fitchburg. *New England J. Med.*, 207, 2:82 (July 14), 1932.

**School Children's Ears**—In a group of nearly 10,000 children, 3.5 per cent showed definite defective hearing. Among them were many with hypertrophied and infected tonsils and adenoids. That this condition cannot be ignored by school authorities is a reasonable conclusion.

FREUND, E. M. Hearing Survey, Public Schools, Albany, N. Y. *New York State J. Med.*, 32, 13:791 (July 1), 1932.

**Heresy About Colds**—Findings that will make the health propagandist

tear his hair are reported in this paper: There was no significant difference in the number or severity of colds suffered by a group of persons who slept with windows only partially open as compared with another group of fresh air enthusiasts who threw their windows wide.

The same was true of groups of persons that exercised outdoors less than 8 and more than 8 hours per week in summer and less than 4 and more than 4 in winter.

GAFNER, W. M. Hardening Procedures and Upper Respiratory Disease (Common Cold). *Am. J. Hyg.*, 16, 1:233 (July), 1932.

**Amebic Dysentery Test**—Studies are reported which show complement fixing substances in persons suffering from amebic dysentery.

HEATHMAN, L. Studies of the Antigenic Properties of Some Free Living and Pathogenic Amebas. *Am. J. Hyg.*, 16, 1:97 (July), 1932.

**Tuberculosis and Pregnancy**—“From the evidence obtained from a study of 470 cases of pulmonary tuberculosis, we conclude that pregnancy does not have a marked effect on the progress of tuberculosis. In fact, the evidence is striking that the phenomena are independent of one another.” So concludes the second of two papers, the first of which finds abortion rarely indicated if adequate treatment is given in pregnancy.

JENNINGS, F. L., *et al.* Pregnancy in the Tuberculous. *Am. Rev. Tuberc.*, 25, 6:673 (June), 1932.

**Mottled Enamel**—The continuous use of domestic water containing 2 p.p.m. of fluorine will result in interference with enamel calcification of the teeth, and the damage will be permanent and irreparable. The only solution is the abandonment of a fluorine tainted water supply.

McKAY, F. S. Tooth Enamel Mottled by

Water. *Water Works Eng.*, 85, 13:790 (June 29), 1932.

**A Milk-Borne Paratyphoid Epidemic**—This Canadian epidemic was caused by faulty operation of a pasteurizing plant which permitted raw milk to be bottled by mistake. The need for adequate supervision of pasteurization is amply demonstrated.

McKAY, A. L., *et al.* An Epidemic of Milk-Borne Paratyphoid Fever. *Canad. Pub. Health J.*, 33, 7:303 (July), 1932.

**Changing Diets**—The author says: “There are signs that many of our adolescents are growing somewhat more rapidly than in former generations. Is this an outcome of our modern education and advertising? Is it a wholesome trend? It is too early to answer these questions with conviction; but it suggests that our menus have indeed changed.”

MENDEL, L. B. The Changing Diet of the American People. *J. A. M. A.*, 99, 2:117 (July 9), 1932.

**Temporary Sanitation**—Sanitarians who may some time be faced with the job of providing temporary sanitary conveniences for large crowds will wish they had read this account of the experience at Yorktown, Va., when 120,000 persons descended upon a town of 480 souls.

MILLER, A. P. Keeping a Celebration Area Clean. *Munic. San.*, 3, 7:280 (July), 1932.

**Gonorrheal Vaginitis**—This symposium on the subject of gonorrheal vulvovaginitis considers the problem from the standpoint of the clinician, the institution, the pediatrician, and the school physician.

NELSON, N. A., *et al.* Gonorrheal Vulvovaginitis. *New England J. Med.*, 207, 3:135 (July 21), 1932.

**Sinuses and Colds**—The conclusion of an X-ray study of nasal sinuses is

that there is no evidence of association between the size of the frontal sinus and the number or duration of attacks of the common cold.

PALMER, C. E. Relation Between Size of Frontal Nasal Sinuses and (1) Attacks of Upper Respiratory Disease (Common Cold) and (2) Certain Nose and Throat Conditions. *Am. J. Hyg.*, 16, 1:224 (July), 1932.

**Childhood Mortality Trends**—The infant mortality rate in upstate New York declined 33 per cent from 1915 to 1928, whereas the drop in the death rate in the age group 1-4 was considerably greater, 47 per cent. After a lot of statistical study the conclusion is reached that those children in the pre-school group are not receiving as much care as infants and school children. If this is so, they certainly seem to thrive on neglect.

PARKHURST, E. Trends in Childhood Mortality in New York State (exclusive of New York City). *New York State J. Med.*, 32, 13:785 (July 1), 1932.

**Drug Addiction**—This epidemiologic study of drug addiction points out that there are both a local and a general responsibility for preventive measures. The federal program is described.

TREADWAY, W. L. Drug Addiction and Measures for Its Prevention in the United States. *J. A. M. A.*, 99, 5:373 (July 30), 1932.

**Dissolved Oxygen Determination**—The Winkler method of determining dissolved oxygen is described in working detail in this committee report.

THERIAULT, E. J., *et al.* The Determination of Dissolved Oxygen by the Winkler Method. *Sewage Works J.*, 4, 3:413 (May), 1932.

**Health Economics**—Here is the promise for a solution to the vexing problems of providing medical care. If intelligent leadership can be given to the forces of social discontent, improved medical and health services may result; so says the Chairman of this highly important commission.

WILBUR, R. L. The Economics of Public Health and Medical Care. *Milbank Quart. Bull.*, 10, 3:169 (July), 1932.

**Fertility of White Women**—"All this evidence seems to show that an important . . . cause of the rising fertility of native-white women since 1900 . . . has been the slow permeation of the class of native-white women within the present century by American-born daughters of foreigners carrying some part of the high fertility of their stock and thus counterbalancing the tendency to a fall in the birth rate of native-white women . . ."

WILCOX, W. F. Changes Since 1900 in the Fertility of Native-White Wives. *Milbank Quart. Bull.*, 10, 3:191 (July), 1932.

# NEWS FROM THE FIELD

## N.T.A. RESEARCH FELLOWSHIP ANNOUNCED

THE National Tuberculosis Association announces Mary E. Bateman as the Research Fellow for the year 1932-1933. Miss Bateman, who has for the past year been connected with the New York State Department of Social Welfare, at Albany, will be a member of the National Tuberculosis Association Committee on Social Research.

## DELTA OMEGA PRESENTS SCROLL AND KEY TO DR. RAVENEL

MAZÏCK P. RAVENEL, M.D., at the banquet of the Delta Omega at Ann Arbor, where he gave an address in July, was presented with the scroll and key of the organization. He is the ninth person who has ever had this conferred upon him.

## HARTLEY AWARD TO DR. PARK

THE public welfare medal, for eminence in application of science to public welfare, was awarded to Dr. William Hallock Park, Fellow A.P.H.A., of New York, for his work as head of the Research Laboratories of the New York City Health Department and as a leader in research and application of scientific discoveries to prevention of disease. This medal is awarded from a fund established in memory of Marcellus Hartley.

## MICHIGAN MIDSUMMER CONFERENCE

THE Midsummer Conference of the Michigan Public Health Association was held in conjunction with the week-end institute at the University of Michigan, Ann Arbor, Mich., July 16. Among the subjects discussed were Heart Disease, Milk, Health Insurance, Dental

Health Service in Schools, and Typhoid Fever. Dr. Ravenel gave an address on Milk.

## PERSONALS

DR. ARTHUR M. JOHNSON has been appointed Health Officer of Rochester, N. Y., to succeed Dr. George W. Goler who resigned on July 1, after 35 years of continuous service. Dr. Johnson has been connected with the Rochester Health Bureau for some time.

MIGUEL CESPEDES ACOSTA, M.D., of Havana, Cuba, member A.P.H.A., was recently appointed Secretary of Sanitation and Charities of the Republic of Cuba. In the announcement of this appointment it was stated that there will be "no political interference in public health affairs, improving the tenure of public health works and an honest administration."

## CONFERENCES

September 6-9, International Union Against Tuberculosis, The Hague.

September 12-19, American Hospital Association, Detroit, Mich.

September 26-October 1, National Congress of Parents and Teachers National Board of Managers, Chicago, Ill.

October 3-7, Twenty-first Annual Safety Congress and Exposition, Washington, D. C.

## Participation of Lay People in the Promotion of a Rural Child Health Program\*

ELMA ROOD, R.N.

*Director of Health Education, Children's Fund of Michigan,  
Detroit, Mich.*

CONDITIONS in the rural field of child health point toward a coöperative program as the only one that can really reach every child. Because the rural territory is large, and the facilities to cover it are small, the limited professional personnel is faced with the overwhelming task of trying to bring a health service to scattered families in isolated districts. Health workers are often under the additional handicaps of inadequate budgets to cover expenditures, and large numbers of children requiring assistance, due not only to the scarcity of medical and dental service, but also to the fact that the poverty of many families makes it impossible for them to provide corrective work.

Child health work is never completed in any community, since each year new children are added to the population, and the health forces must try to keep abreast of a steadily moving procession of children, many of whom live long distances from the health centers. Thus it is that the only possible way adequately to reach these children is to multiply the influence of professional groups by enlisting the coöperation of the people of the local community.

Many procedures which trained workers have formerly believed belonged exclusively within their province, can be done equally well

---

\* To be read before the Child Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting at Washington, D. C., October 27, 1932.

by an intelligent lay person (one who has had no specialized training in that particular field). So, in order that the public dollar may go as far as possible, professional workers should ascertain the minimum number of procedures that they must carry on personally, and turn over all others to competent citizens. Then too, lay people have a much greater appreciation of the importance of a service after they have participated in it; therefore, the time spent in educating local leaders is well spent, when measured in terms of increased service to the child.

It is from the community itself, then, that its own greatest good can come, since Mrs. Everybody and Mr. Ordinary are in the majority and can help more than they realize. For example, they can care for the transportation of indigent children to places where various types of health service are available. When physical examinations are being given in a community center; when dental clinics are operating; when a station for immunization has been opened, half the battle for health is won. But only half, for, how are the children who live from 4 to 10 miles from these advantages to derive any benefit from them? With the public health officials working to capacity, the hours spent in conveying children to and from such centers are sacrificed from other professional duties for the children. Then it is that a volunteer transportation service is instituted by some competent citizen who is willing to contribute his or her car and a morning a week to the cause, thus insuring to every child in the district the best health advantages that the community offers.

For the citizen who is eager to help and has no car, there are various other tasks. In districts where there are poverty stricken families, intelligent women can carry on relief programs under the supervision of the child health committee or some social agency, if there is one. They can promote child health by reporting to the authorities all children who should be classed as indigent. They can gather and remake clothing to outfit these children, thus protecting them from possible illness due to exposure.

Many bands of community women have utilized their social gatherings for worthwhile purposes and have contributed labor, and raised the necessary money to support such enterprises as providing undernourished children with milk and cod liver oil, and preparing materials for loan closets, layettes and maternity kits.

All citizens can participate in reporting special cases requiring attention, thus enabling the health authorities to work to greater advantage, because the community itself has become an information bureau. Another indispensable factor is that of publicity. Every

interested parent in a rural district who acquaints the public with the value of child health work is furthering the cause. This enthusiastic and optimistic oral propaganda is far reaching in its effects, and supplements the work of the local newspaper.

Occasionally the small centers come together in a county-wide celebration or assembly (as May Day) and each district interprets to the others its own progress in carrying out the health program. Such an exchange of suggestions is stimulating and helps the local leaders to see their parts in the whole scheme, and to visualize the broad field that the health service offers.

Apart from the average citizens, it is assumed that the county officials and administrators will contribute much to the success of the program. School superintendents arrange for space and time for health procedures, and other officials work shoulder to shoulder with the entire community in the interest of the children.

Then there are the teachers. Their influence is an especially broad one because they have daily contacts with so many children. The resourceful teacher makes a survey of the physical condition of the children and the school environment early in the year, and makes immediate adjustments for special cases and conditions disclosed. She utilizes, as opportunities of teaching, the daily events and problems which arise in the school, thus enabling pupils to coöperate intelligently in the prevention and care of colds, epidemics and accidents. She seeks to combat undernourishment in children by instituting hot lunches, and she endeavors to instil in each child the desire to be in as perfect a physical condition as is possible.

In her contacts with the parents, the teacher often educates them in special phases of the school health program such as physical examinations and immunity treatments. For the protection of the community, the teacher reports any signs of departure from normal health which may appear in the classroom from day to day. She can often give valuable information regarding the particular needs of certain children, and her word carries weight in an interview with the county officials in the interest of special cases. The alert, interested teacher can in these and in innumerable other ways interpret the health service to the entire district and help it to function efficiently.

These are some of the ways in which officials, teachers, and citizens can work together in the common cause. The extent to which lay people actually participate in the program depends upon a variety of factors, some of which are inherent in the community, and some of which may be developed. A neighborly interest, with a

desire to be of service to others, is latent in almost every district. It manifests itself readily in times of disaster, because the emotions are involved; but in the everyday occurrences in the community, the citizens are inclined to be casual until some threatened danger brings matters to a crisis. This driving force which is so potent in time of stress and strain should be called into action when there are less dramatic situations demanding help. When people are brought to realize fully that undernourished children who are in their midst continually are literally starving, or that those who are laboring under various handicaps of vision or hearing, are really suffering, they will work together with the same neighborliness and sympathy which they exert under more dramatic circumstances.

A friendly spirit built up between the health workers and the people is absolutely essential, and both should feel that they are coworkers in a common cause, and realize that the success of one is very much dependent upon the assistance of the other.

An organization for work is another prerequisite, and it should reach even the most remote rural areas. Potential executive ability in the community should be recognized in this organization, and increasingly given new responsibilities for the management of selected projects. The professional group too must have good leadership if things are to be accomplished. A good leader must be able to define aims clearly, to point out the best road leading to the community's goal, and he must be able to select and to detail many responsibilities to others. The contributors must see their parts in the realization of the end result, and feel that their participation has been worthwhile and is appreciated.

Finally, the professional group should give generous recognition to the lay service; in speeches or messages the officials should avoid the personal pronoun "I," and in discussing accomplishments should say "we" or "they" (the lay people) "have done these things." Newspaper articles and official reports should keep the spotlight on the people whenever possible in order that the public may realize that it is absolutely indispensable in the program. In this way, the citizens will be brought to realize that they hold in their hands the physical condition of their own and their neighbor's children, and that with the proper spirit of coöperation and coördination among themselves and with the authorities, the possibilities are infinite for insuring a high degree of health for the maximum number of children.

Some of these "infinite possibilities" are being realized, and in isolated districts where one might least expect to find a coöperative interest in health. For example, there is Pumpkin Creek's loan closet

mothers for their first visit to the school. The toddlers were given a complete health examination; luncheon consisting of orange juice and animal crackers was served for them; and the mothers were advised as to the proper food and care of preschool children. The adventure was an unqualified success, and has become an annual event that these children may be kept healthy and fine until they are added to the school population.

In a poverty stricken consolidated district the school principal was appalled by the high percentage of children who were under-nourished. Many of them were actually hungry, because the meager little farms on which they lived had gone to seed, and the depression had made it impossible for their farmer fathers to realize any profits on their products. The principal decided that it was the school's responsibility to see that every child had at least one good meal every day. Accordingly, he had a canvass made of the entire district, each home checking the farm produce which it could contribute to a hot lunch for the children. On the basis of this, he worked out a schedule for meals costing 3 cents apiece, and for the entire year 285 children had a hot meal every day. The home economics girls did the work and 95 per cent of the homes coöperated with donations of potatoes, milk, turnips, carrots, and beets. All of the children gained noticeably and the parents were delighted. When the principal sent around a questionnaire to see whether the district wished to continue "feeding the small army" the following year, every reply was an enthusiastic affirmative, and one mother wrote delightedly: "By all means! All of the children are fatter, especially Beulah!"

So we see that the "learning by doing" theory in education, which is coming to be generally accepted in childhood education, is thus beginning to be recognized as equally valuable in educating adults to the problems about them and how to solve them most effectively.

These, then, are the actual by-products of coöperative enterprises, and in terms of child health their value is inestimable. Small armies are fed; the toddlers are inspected, and a checking account is opened in the community. And in every case the district shows a marked improvement; the general community is healthier, and the layman learns that he does not need specialized training to contribute his share.

If, all over the rural areas, citizens could join hands in such a way with health departments, both would be doubly strong and their combined forces could accomplish the hitherto impossible feat of bringing maximum health to every boy and girl in the remotest districts.

# H and O Agglutination as an Aid to the Diagnosis of Typhoid Fever

ANNA DEAN DULANEY, PH.D., WALTER T. WIKLE AND  
RUBY TRIGG

*Department of Bacteriology, University of Tennessee College of Medicine,  
Memphis, Tenn.*

DURING the past year we have determined the H and O titers of 161 serums, using formalinized and alcoholized suspensions of *B. typhosus*, for the purpose of evaluating such a procedure in the diagnosis of typhoid fever. These serums represent 41 cases of clinical typhoid, 30 patients suffering from febrile, non-typhoid diseases, and 90 healthy vaccinated (antityphoid) individuals. The results of these titrations are presented in Tables I and II.

According to Felix,<sup>1</sup> most typhoid infections produce both H and O agglutinins—the H (flagellar) designating the infecting organism, and the O (somatic) expressing the body's response to infection. In the course of typhoid fever resulting in recovery, Felix demonstrated a marked development of O agglutinins early in the disease. Overwhelming infections would not permit the body to produce O agglutinins and, on the other hand, very slight infections would not offer sufficient stimulation for the development of O agglutinins to any appreciable titer. Thus the demonstration of small flaking O agglutinins in a suitable dilution of serum (1:100–1:200) has diagnostic value and, in addition, offers some prognostic information since Felix and Olitzki<sup>2</sup> regard the O agglutinin as identical with the bactericidal antibody. In vaccination only large flaking (H) agglutinins are produced. A vaccinated person suffering from some non-typhoid disease may show a stimulation of H agglutinins (anamnesic reaction), but O agglutination is only given in the course of infection with a member of the enteric group of organisms.

Felix's demonstration of high titers of O agglutinins in typhoid infections has been confirmed by Stuart and Krikorian,<sup>3</sup> Gardner,<sup>4</sup> Ecker and O'Neal,<sup>5</sup> Mudd,<sup>6</sup> and workers in this laboratory.<sup>7, 8</sup> Stuart and Krikorian also agree with him as to the lack of O agglutinins in vaccination. All other data, however, substantiate Gardner's claims that vaccination produces O agglutinins to a degree worthy of notice.

Mudd demonstrated a definite correlation between the protective power of a T.A.B. vaccine and its ability to stimulate the development of somatic agglutinins. Gardner recommends the use of higher serum dilutions (1:400) than those used by Felix to insure the diagnostic value of O agglutination.

#### PROCEDURE

*Serums*—Blood was drawn from febrile patients as soon after admission to the Memphis General Hospital as was possible. When the clinical and laboratory findings designated typhoid fever subsequent specimens of blood were taken at intervals depending on the condition of the patient and the duration of stay in the hospital. It was hoped that repeated titrations would show a relative increase in the development of H and O agglutinins. Since this hospital does not see many early cases of typhoid we were not able to demonstrate any very significant fluctuation of agglutinins, and only the results of the first titration are considered here. The 30 serums from patients suffering from non-typhoid febrile diseases serve as controls for the patients with proved typhoid. Serums for the study of the agglutination reaction in vaccination were obtained from students of the class in medical bacteriology.

*Antigens*—A 0.1 per cent formalinized antigen as recommended by Dreyer,<sup>9</sup> and an alcoholized antigen prepared according to Gardner's<sup>4</sup> method were employed for the tests reported here. A strain of typhoid isolated from the blood stream of a patient 6 months previously, and conforming to all requirements of a smooth motile form was used in the preparation of the antigens. Recently we have found

TABLE I

SHOWING H AND O TITERS OBTAINED WITH 161 SERUMS FROM VARIOUS SOURCES

Number of Serums	Source	Type of Agglutination	Number of Serums Giving Titers Indicated								
			Neg.	40	80	160	320	640	1,280	2,560	5,120
41	Typhoid Patients	H	1	1	2	6	5	11	8	3	4
		O	1		2	2	1	8	13	9	5
30	Non-Typhoid Febrile Diseases	H	15	8	5	2					
		O	19	4		4	3				
90	Vaccinated Individuals	H	8	2	8	18	21	9	18	6	
		O	17	21	29	18	5				

that 1 per cent formalinized antigens are better for detecting H agglutination than those containing lower proportions of formalin. Formalin 0.1 per cent does not entirely inhibit O agglutination and it is felt that some of our agglutinations in high dilutions of serums with formalinized antigen may in reality be O agglutination, which was not inhibited by the formalin concentration employed.

*Technic*—Macroscopic agglutinations were set up with serum dilutions ranging from 1:20 to 1:2,560. The antigen-serum mixtures (0.5 c.c. each) were incubated in a water bath at 52° C. The H agglutinations were read after 2 hours, the O at the end of 24 hours in the water bath and again after 24 hours in the refrigerator. Final readings were made by lamplight and with the aid of a hand lens.

### RESULTS

As shown in Tables I and II, there is a marked development of both H and O agglutinins in most cases of typhoid fever. The results obtained in other febrile diseases offer a marked contrast. In vaccination H agglutinins are stimulated to high titers, but O agglutinins were present in 81 per cent of the serums tested.

TABLE II

#### SUMMARY OF H AND O AGGLUTINATION IN 161 SERUMS STUDIED

##### *Serums from Typhoid Patients*

Per cent of Serums	Agglutination
2	Neither H nor O agglutination
98	Both H and O agglutination
59	Higher O than H agglutination
12	Higher H than O agglutination
27	Approximately equal H and O agglutination
87.5	O agglutination exceeding 1-500

##### *Serums from Non-typhoid Febrile Patients with no History of Vaccination*

Per cent of Serums	Agglutination
0	O agglutination to 1-500
23	O agglutination exceeding 1-100

##### *Serums from Vaccinated Individuals*

Per cent of Serums	Agglutination
91	H agglutination 1-40 or over
81	O agglutination 1-40 or over
26	O agglutination exceeding 1-100
0	O agglutination to 1-500

The relationship of O agglutination to infection seems definite, but the titers of 1:100 and 1:200 as suggested by Felix are not sufficiently high to be specific since the 1:100 titer was exceeded by

23 per cent in the non-typhoid group and in 26 per cent of vaccinated subjects.

It will be seen that 87.5 per cent of the typhoid patients agglutinated the O antigen in serum dilutions of 1-500 and such a dilution might arbitrarily be accepted as indicative of infection regardless of vaccine history.

The ease of preparation of antigens and their stability recommends H and O agglutination as a laboratory procedure in the diagnosis of typhoid fever, although it could never have the validity of the isolation of the causative organism.

### CONCLUSIONS

1. Both H and O agglutinins are produced in typhoid fever.
2. O agglutination in high titers (1-500 or greater) is very suggestive of typhoid infection.
3. Lower titers do not rule out O agglutination due to related infections or vaccination.

## Care of the Feet

ALL workers in factories where there is a medical department should be given an opportunity to examine a skeleton of the foot which at the same time should be explained to them. This would prevent much misuse of the foot, improper shoes, etc. In particular, fatigue reduction would follow.

A discussion is presented on the general principles of standing, production of falling arches, varicose veins, the proper gait, the value of the foot bath, and description of so-called corrective exercises which can be carried out at nights.—May R. Mayers, *Indust. Bull.*, New York Dept. of Labor, Albany, 11, 7:226, 237 (Apr.), 1932.

# Significance of Infant Mortality Data in Appraisal of an Urban Community\*

A. D. H. KAPLAN, PH.D.

*Denver, Colo.*

THE records of 1915 put the infant mortality rate of the United States registration area at 99.9 per 1,000 live births. For that year Denver made respectable comparison, with an infant death rate of 91.3.

Since that time Denver has furnished impressive examples of civic consciousness and growth. It has expanded its hospital and sanitary facilities; converted its public dumping grounds into parks and boulevards; completed a Civic Center widely celebrated; and erected palatial school buildings to excite the admiration of visiting school administrators.

Nevertheless, from 1915 to 1928 the registration area of the United States as a whole had been achieving consistent improvement in its infant mortality rate until the figure had been brought down below 70 per 1,000. The death rate of the 25 largest cities of the country now stood at 66.5; Seattle and Portland led the march of progress with a rate of 43. At the bottom of the list was Denver; her infant death rate in 1928 was still at 91, where it had been in 1915.

The infant mortality study in Denver may be construed as an effort to solve the paradox of a city noted for its beauty, cleanliness, and civic pride, suffering an infant death rate higher than that of any other American city of its class.

Those responsible for the investigation recognized that there would be little justification for the undertaking if it were just another tabulation of general causes of infant mortality. What was required was an analysis of the community, as comprehensive as practicable, which might help to uncover those factors in Denver's infant mortality problem that were amenable to preventive measures or improvement. The composition of the population, the housing conditions, and the sanitary facilities of each district were to be studied for their bearing on infant mortality. A questionnaire, evolved after consultation with physicians, nurses, and health officers, and a month's trial in the

---

\* Read at the Third Annual Meeting of the Western Branch American Public Health Association, at Denver, Colo., June 9, 1932

field, reflects the effort to obtain an adequate basis for significant conclusions.

The study embraces every live birth and stillbirth in the city of Denver during the 12 months ending February 28, 1931, and each infant death within that group of live births. The total of the live births was 5,330; of stillbirths 180, of infant deaths 410, of maternal deaths 41. The stillbirth rate was 33.8 per 1,000 live births. The mortality rate on the live births was 77 per 1,000 live births.

Of the deliveries in Denver during the 12 months 895 were non-Denver cases, 16.8 per cent of the total. Deaths may have occurred within this out-of-town group during the infancy year; some of these, of course, would not be tracked down by our study. We are reasonably certain that we have all deaths which occurred among the out-of-town cases within 2 weeks after birth—33. The Denver resident deaths during the first 2 weeks were 179, against a total of 350 infant deaths for the year. Assuming, between the 2-week and the annual figures, the same proportion among the out-of-town cases as we have for the resident group, we estimate the number of infant deaths for the out-of-town group during the year to be 65, giving them a mortality rate of 73 per 1,000. Before the year was over we actually obtained information on 55 deaths from this group, leaving us 10 short of our estimated quota. The resident cases showed an infant death rate of 80 per 1,000.

Denver's apparent infant mortality rate, for births within the period of our study, is 87; the higher "official" figure is due to the intake by the Health Department of 55 death certificates of babies that died in Denver but were not born there.\* This intake is an excess of 45 over the number of additional deaths that our estimate would require against the out-of-town cases that were delivered in Denver, and would hardly be considered within the purview of any general efforts to reduce Denver's infant mortality.

The interrelations developed among 5,500 questionnaires, each containing 150 items of medical and social data, are evidently beyond the scope of a 30-minute discussion. This paper has been confined, therefore, to some data on the distribution of significant general factors among the districts and distinctive groups of the city. The objective is to illustrate how the infant mortality problem reflects the social and economic conditions of the community.

In Figure I we see the 33 districts into which the city is divided for social service purposes. The black areas represent the districts

\* The number of death certificates received by the Health Department on cases not delivered in Denver, 55, happens to be the same as the number of Denver death certificates on the out-of-town cases delivered in Denver and included in the study. But the two items are distinct.

in which the infant mortality rate was 100 per 1,000 or over. The dark cross-hatched areas show the districts with infant mortality rates ranging from 75 to 100; the light cross-hatched lines are used for the districts with rates from 50 to 75, while the lightly stippled areas are the banner districts, having less than 50 infant deaths per 1,000 live births. The map is based on the data in Table I, giving the distribution of infant mortality by districts.

It will be seen that wide differences exist in the infant mortality of Denver's various districts, ranging from 24 per 1,000 in District A to 210 in District K; 21 districts show a mortality above the average. A composite of the 5 best districts gives them 18 deaths out of 566 live births, or a rate of 32 per 1,000. The 5 most unfavorable districts give 101 deaths out of 532 live births, a rate of 190 per 1,000. The black districts form a continuous area in the "bottoms" along the Platte River. Paralleling this area are the railroad yards; overhead are viaducts which carry traffic between the east and west sides of Denver. It is this part of the city in which incomes are lowest, poor shacks predominate, sewers are lacking, toilet facilities are

FIGURE I—INFANT DEATH RATE BY DISTRICTS

TABLE I  
DEATH RATES BY DISTRICTS

District	Infant deaths			District	Infant deaths		
	No. of live births	Number	Rate per 1,000 live births		No. of live births	Number	Rate per 1,000 live births

T	219	13	59				
U	112	5	45	Grand Total	5,330	410	77

primitive, and the highest percentage of unemployment exists. It is an area largely unknown to the residents "on the hill," who have comfortably held to the assumption that Denver is a city without slums.

#### HOUSING

In a study made for the Denver Real Estate Exchange in 1930\* data were obtained concerning the number of those living units in the city appraised by the municipality at less than \$200. Figure II indicates the location of these shacks throughout the city. The shacks—those constructed prior to 1901—are shown by solid black dots, each dot representing ten such units. The circles represent homes appraised at less than \$200 which are of more recent construction and in a better state of repair.

Again we find our submerged district along the Platte River, with a predominance of old shacks in the region that showed the highest death rate. The greatest concentration of old shacks is found in District G—224 in number. A tour of the district reveals several

\* See *Real Estate Inventory and Market Survey of the City and County of Denver, Colorado, as of September, 1930* published by the University of Denver Bureau of Business and Social Research for the Denver Real Estate Exchange.

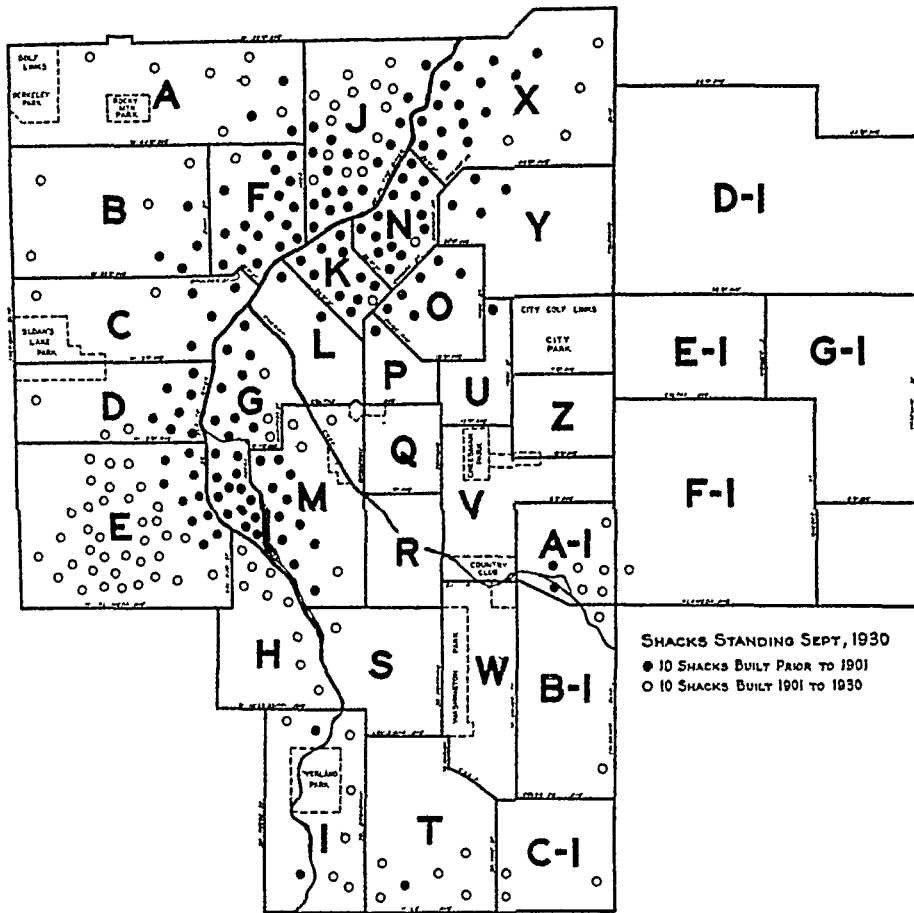

FIGURE II—LOCATION OF SHACK-HOUSING, SEPTEMBER, 1930

hundred shacks of somewhat more recent origin which are hardly more fit for habitation than are the older 1-room dwellings. Indeed it has been found that 86.2 per cent of all the homes in District G, 90.8 per cent of those in District N, and 89.1 per cent of those in District K were built prior to 1901.

The division of the homes of nominal appraisal into those of newer and older construction, respectively, sheds some light on the apparent paradox that District E, adjoining the Platte River on the northeast, had a death rate of only 59 per 1,000. In general, the houses of low appraisal in this district are away from the river bottoms; they represent modest homes built on large plots of ground, frequently constructed by the residents themselves. It is a district of permanent residents who have purchased their inexpensive lots, in contrast to the shifting population of the congested shacks in the 5 districts along the "bottoms."

The 5 districts which showed the lowest infant death rate contain 182 out of 2,713 shacks for the city as a whole, 6.7 per cent of the total.

## ANNUAL RATE VERSUS EARLY INFANCY RATE

The 1930 infant mortality data for the country as a whole have not yet been released; but if we compare the 1929 United States infant mortality rate of 67.6 with the Denver rate of 77 per 1,000, and then compare the corresponding 24-hour death rate of the nation, which was 15.3, with Denver's, 26 per 1,000, we realize that the city of Denver has an unduly large percentage of deaths under 1 day, as compared with its annual rate. Where the United States rate for the first 24 hours was 22.6 per cent of the total mortality for the year, Denver's 24-hour rate was 31.3 per cent of its annual infant death rate. This suggests the desirability of a careful medical analysis of local practice in deliveries.\*

There is a striking contrast between the relative importance of the early infancy mortality in the poor sections, and that of the better districts of the city. If we consider the 5 districts along the Platte River, which account for the greatest number of infant deaths, we find that only 21 of their 109 occurred during the first 24 hours. Their 24-hour death rate was less than one-fifth of their yearly rate. When we take the 5 most favorable districts of the city, with a total of 23 deaths, we have 12 of them within the first 24 hours: *i.e.*, more than one-half of the infant mortality in these 5 best districts occurred during the first 24 hours. The favorable districts suffered slight loss among the babies that lived past the first 24 hours; the poor districts had the preponderance of their losses as the year advanced.

## RACIAL FACTORS

The bulk of Denver's negro population is in District O, which accounted for 65 of the 91 negro live births in the entire city. Here a noteworthy record has been made, with only 1 negro infant death among the 65 deliveries, a rate of 15 per 1,000. The infant mortality rate for all of Denver's negro births was 63 per 1,000. By way of accounting for the few deaths among the colored cases in District O, two suggestions occur: an infant welfare station of the Visiting Nurse Association is located in the negro section, open to all women in the district; there were 138 white births in District O, as against 65 negro births, but the records of the welfare station indicate that 80 per cent of the expectant mothers availing themselves of the facilities for prenatal care were negroes. They enjoy, for the most part, favorable housing conditions, occupying homes in a section that used to be tenanted by the upper middle class of the white population, before the whites gave way to the influx of negroes into the district.

\* The obstetrical data on this phase of our study have not yet been fully broken down; they are now in process of analysis.

The antithesis of the negro situation is furnished by the high infant mortality record of the Spanish-speaking, usually referred to as the Mexican, population. The aggregate of Mexican births for the 12-month period was 294, of which 277 were assignable to definite districts. Of this group there were 185, about two-thirds of the total Mexican births, in districts F, G, K, and N. In this area the composite Mexican infant mortality rate was 232, nearly treble the rate of 81.7 for the non-Mexican population. For all Mexican live births in the city the infant death rate was 206. The Mexican stillbirths were likewise out of line, with 61 per 1,000 live births. Though the Mexicans constitute approximately 3 per cent of the Denver population, they furnished 6 per cent of the city's total births, and they accounted for 14 per cent of the infant deaths. It is obvious, therefore, that in any effective campaign to reduce Denver's infant death rate, particular attention will have to be given to the Mexican sections.

#### FAMILY INCOME

That there is a progressive concentration of infant mortality in the poorer districts as the year advances, seems to be borne out in the consideration of infant deaths by income levels. If we separate the 2-week record from the data for the balance of the year, at the various income levels, we have the picture shown in Table II.

Clearly the trend is a closing-in of the gap between the 2 weeks' mortality and the yearly mortality, as we go from the lower to the higher income levels. In the lowest income group, the loss after the second week is more than twice that of the first fortnight. In the highest income class, the additional deaths after the first 2 weeks represent only 11.1 per cent of the yearly mortality.

The income data appear to confirm, on the whole, the familiar tendency for infant mortality to increase with the decline in income levels. This is especially true as we approach the lowest levels of self-support. For that section of Denver's population having family incomes under \$500, the infant mortality rate is 186 per 1,000 live births. (This high rate is obtained despite the fact that the class in question includes the charitable cases, in the group under \$250, which with the aid of public medical care and public relief manages to hold its infant mortality rate at 72.) For the income class of \$3,000 and over, the infant death rate is only 25 per 1,000 (see Table III).

In the breakdown of income levels by districts, we come upon a low income area which comprises the same districts that stood out in Figure I as having the highest infant death rate in the city. Every

TABLE II

<i>Income</i>	<i>Number of infant deaths</i>	<i>Infant death rate per 1,000 live births</i>	<i>Income</i>	<i>Number of infant deaths</i>	<i>Infant death rate per 1,000 live births</i>
Under \$500			\$2,000 and under \$2,500		
Under 2 weeks	14	51	Under 2 weeks	11	27
2 weeks to 1 year	34	125	2 weeks to 1 year	7	17
Total	48	176	Total	18	44
\$500 and under \$1,000			\$2,500 and under \$3,000		
Under 2 weeks	31	37	Under 2 weeks	8	33
2 weeks to 1 year	49	59	2 weeks to 1 year	4	16
Total	80	96	Total	12	49
\$1,000 and under \$1,500			\$3,000 and above		
Under 2 weeks	47	43	Under 2 weeks	8	22
2 weeks to 1 year	31	28	2 weeks to 1 year	1	3
Total	78	71	Total	9	25
\$1,500 and under \$2,000			All income groups (in- cluding Not Reported)		
Under 2 weeks	22	28	Under 2 weeks	216	41
2 weeks to 1 year	23	29	2 weeks to 1 year	188	35
Total	45	57	Total	404	76

district with a death rate of 50 or less is in the income level above \$1,500. From there on such factors as the *para*\* of the child, age of the mother, etc., have been found to modify the relationship between income and infant mortality.

#### BIRTH RATES

Our data on incomes and birth rates do not correlate consistently with infant mortality in all districts. An accurate census of the population by districts is not available, but we know the number of living units in each district as of 1930,† and may therefore offer some rough comparisons on that basis. The 3 districts of highest infant mortality were Districts G 203, K 210, and N 181. These in turn

\* By the term *para* the offspring of a given mother are distinguished. Para No. 1, for example, is the first "life" created in the mother's womb; para No. 2 is the second, and so on. For this purpose, abortions, stillbirths, and live births are counted. In the case of multiple births, a number is given to each of the offspring in the order of its birth. In other studies of infant mortality, notably the recent British study "On the Relative Value of the Factors which Influence Infant Welfare" (University of London, Eugenics Laboratory Memoirs. XXV), the numerical order of the infant is referred to as *place in the family*. That expression, however, has social implications which might exclude the illegitimate births, or the offspring of a previous marriage that have no place in the present family. It has seemed more feasible, as well as convenient, to express the desired meaning, in the present manuscript and tables, by using simply the term *para*.

† University of Denver Bureau of Business and Social Research, *op. cit.*

TABLE III  
INFANT MORTALITY AND AVERAGE PARA BY INCOME GROUPS

<i>Annual family income</i>	<i>Number of Live births</i>	<i>Deaths</i>	<i>Death rate per 1,000 live births</i>	<i>Average para</i>
Under \$250 *	56	4	72	4.12
\$ 250 to \$ 500	218	44	202	3.71
500 to 750	398	40	101	3.18
750 to 1,000	440	40	91	2.96
1,000 to 1,250	767	58	76	2.70
1,250 to 1,500	337	20	59	2.60
1,500 to 2,000	790	45	57	2.42
2,000 to 2,500	408	18	44	2.22
2,500 to 3,000	247	12	49	2.36

All incomes	5,330	410	77	2.54

\* Charity cases included.

† Based upon 1,173 cases only, since para information was lacking on 133 cases in this group.

show the highest number of births relative to living units, as follows: District G—172 births in 1,336 living units, District K—100 in 877, and District N—149 in 1,575. Combining these 3 districts we get 111 births per 1,000 living units, by far the highest birth rates for any 3 districts in the city. These are at the same time the ones which rank lowest in average income.

Against these we have a contrast in the 3 residence districts of lowest birth rates, namely, Districts Q, U, and E-1, with a composite birth rate of 37 per 1,000 living units. Their infant mortality rates are third, sixth, and second, respectively, from the lowest. In income they rank third, fourth, and second, respectively.\*

An unmistakable tendency in our data is for the higher income classes to show low birth rates and *vice versa*. This will be evident from a glance at Table III, which gives the average *para* of the births at each income level. When we break down the infant mortality record by the *para* of the child we find little difference in infant mortality rates for paras 1 to 5. But a sharp rise in the death rate occurs from *para* 5 on. The average death rate for paras 1 to 4 inclusive, is 67 per 1,000 live births, while for paras 5 and over we have an infant mortality record of 143 per 1,000 live births. The infant mortality rate for each *para* is shown below. As to the general relation of

\* It does not follow, however, that we have no examples of large families and moderate incomes going hand in hand with low mortality. The most striking case in point is that of District A, with a birth rate of 64 per 1,000 living units and a median income level only a little above \$1,500, leading the districts with an infant mortality of only 24. It is a district free from congestion, containing two of the city's largest parks, and detached homes of established residents at an almost uniformly middle-class level. On the other hand, we have District Z quite out of line in the other direction, with 11 deaths in 119 live births for an infant death rate of 92, although its birth rate is only 43, and its district income is fifth from the highest.

infant death rates to birth rates and income, a permissible conclusion is that high para and low income, when found together, mean a high infant mortality.

#### CAUSES OF DEATH

The ranking of the leading causes of death is the same for Denver's cases as it is for the United States, as may be seen in Figure III. Three items, however, command attention. The first is the relatively high incidence of prematurity in Denver, constituting 32.2 per cent of the infant deaths. The prematurity death rate for Denver is 24.6 per 1,000 live births, against 17.4 (1927-1928 average) for the country as a whole.\* The second feature to command our interest is the record on pneumonia and other respiratory diseases. Denver's infant deaths from pneumonia account for 18 per cent of the total infant mortality, while for the United States the incidence of pneumonia is 13 per cent. Expressed as rates, Denver's infant mortality from pneumonia is 14 per 1,000 live births, while for the country at large it has been 8.9 (1927-1928 average). In connection

\* In discussing this paper at the western meeting of the A.P.H.A. Dr. John W. Ames made pointed reference to the prevalence of prematurity on Denver death certificates, as follows: "The term 'prematurity' often appears as the last resort of the careless, untrained accoucheur, hurried (or harried) into a diagnosis by some distracted parent or insistent funeral director. As a matter of fact we may well doubt the accuracy of such a decision in many of these cases; it is entirely conceivable that many of these deaths are due to birth injury, such as intracranial, pulmonary or gastrointestinal hemorrhage which a few moments of intelligent investigation would reveal. Even with post-mortem examination refused (as it usually is) lumbar, ventricular, or cisterna puncture will often clear the situation immediately. The fact, developed by Dr. Earp and me in conference with physicians on this matter, that practically all diagnoses of prematurity have been made by poorly trained obstetricians not attached to our teaching hospitals is illuminating. In any event, in spite of the obvious weakness in our Nomenclature of Disease, if the term prematurity or immaturity is used, it should, on occasion, be qualified. One could say, for example, 'death from prematurity, by reason of multiple pregnancy, from nephritis, heart disease, exophthalmic goiter, diabetes, pneumonia, tuberculosis, etc.,' in the mother. If in doubt, he can always turn the case over to the coroner's physician.

"It is obvious that with nearly 50 per cent increase in mortality during these early weeks of life we cannot hope in Denver to bring our ratio to any fair approximation with those of comparable cities in the United States."

FIGURE III

with the records on diarrhea and enteritis the relative importance of these factors for Denver generally is seen to be in line with that of the nation.

Among the Spanish speaking population of the city diarrhea and enteritis rank as a first cause of infant mortality, with 34 per cent of all the Mexican infant deaths due to this cause. The pneumonia mortality likewise falls most heavily on the Mexican group, accounting for 33 per cent of all the infant deaths. In other words, these two causes combined account for two-thirds of all the Mexican mortality in Denver. In view of the fact that this group occupies the poorest housing section of the city there seems to be room for a pointed inference in the case of the Mexicans regarding the relation between poor housing and sanitary conditions and high infant mor-

tality. An unexpected finding of the study is the infrequency of tuberculosis as a cause of infant mortality, with 1 case in 410 deaths. The United States census for 1928 showed 1,227 infant deaths due to tuberculosis, equivalent to 8 of every 1,000. The fact that tuberculosis as a cause of infant deaths thus ranked lower for Denver than for the United States registration area as a whole, is contrary to the commonly held assumption that tuberculosis would have an important bearing on infant mortality in Denver.

#### PRENATAL CARE

From a statistical standpoint, some of the most satisfactory data in the study have been found in the correlation of prenatal visits and infant mortality. Taking the whole sample, we get a record of infant deaths by prenatal visits shown in Table V.

TABLE V  
INFANT MORTALITY IN DENVER CLASSIFIED BY PRENATAL VISITS

<i>No. of prenatal visits</i>	<i>Live births</i>	<i>No. of deaths</i>	<i>Infant mortality rate</i>
None	375	74	198
1 or 2	846	109	129
3 or 4	692	73	105
5 or 6	678	49	72
7 or 8	758	33	44
9 or more	1,162	35	30

Table VI shows the percentage distribution of prenatal visits among the stillbirths, the live birth deaths, and the live births exclusive of deaths.

TABLE VI  
PERCENTAGE DISTRIBUTION OF PRENATAL VISITS

<i>No. of visits</i>	<i>Live births exclusive of deaths</i>		<i>Live birth deaths</i>		<i>Stillbirths</i>	
	<i>Number</i>	<i>Percentage</i>	<i>Number</i>	<i>Percentage</i>	<i>Number</i>	<i>Percentage</i>
None	299	6.1	74	18.0	24	13.5
1 or 2	737	15.0	109	26.6	36	20.2
3 or 4	619	12.6	73	17.8	32	18.0
5 or 6	629	12.8	49	12.0	20	11.2
7 or 8	725	14.7	32	7.8	28	15.7
9 or more	1,127	22.9	35	8.5	24	13.5
Not reported	784	15.9	38	9.3	14	7.9
Total	4,920	100.0	410	100.0	178	100.0

As might be expected the small number of prenatal visits is found to predominate among the stillbirths and live birth deaths, while most of the infants who lived through their first year were born to mothers who had had the benefit of 5 or more prenatal visits.

While a large number of the cases undoubtedly must be listed with the unavoidable hazards of life and death, it is believed that

Denver's high infant mortality can be made to yield substantially to corrective efforts. At this stage it is already clear that the city requires relief from the archaic housing conditions that obtain in the "Shacktown" area along the Platte River. The mayor and the manager of public health have already made use of the charts prepared under the study, for the elimination of 318 of the least inhabitable old shacks. The city auditor has advised the writer that in the condemnation of these undesirable houses not a single suit has had to be defended in the courts. The Denver Real Estate Exchange has coöperated to the extent of obtaining the lowest possible rents for the displaced families in housing of a better grade. The city has also coöperated with the Citizens' Unemployment Committee by providing emergency employment repairing dilapidated open ash pits, tearing down insanitary out-houses and clearing backyards, in a general effort to raise the housing level among those who do not appear to be able to help themselves.

These preliminary steps, taken shortly after the housing data were released to the city health authorities will, it is hoped, pave the way to a more comprehensive program in respect to other aspects of the study. A few examples suggest themselves: The Mexican population, whose settlement in Denver is a response to the needs of the beet sugar industry, offers a special problem in the adjustment of a simple, rural folk to urban conditions. The loose employment of "Prematurity" as a convenient diagnosis in early deaths, coupled with the relatively high proportion of deaths under 1 day in Denver, suggests the need of a closer follow-up of the causes of mortality in early infancy. If early prenatal care is a matter of general concern, the problem of saving apparently well-born infants looms as a neglected factor especially applicable to the submerged classes of the population.

Among those who have actively participated in this study, the feeling prevails that an analysis of the infant mortality of a community offers significant clues to its more general social and economic problems.

NOTE: The writer wishes to acknowledge that the collaboration of Professor F. L. Carmichael, director of the Statistical Laboratory in the Bureau of Business and Social Research, University of Denver, is reflected in the statistical material supporting this paper. Research Fellows of the Bureau, who have coöperated in the tabulation of the data, include Jesse R. Wood, Jr., Raymond Nassimbene, Alice B. Lester, and Helene Sipprelle. The field investigations were made by the staff of the Denver Visiting Nurses Association, and supervised by Dorothy Watkins Conrad, R.N.

# Effect of Hyperpyrexia Induced by an Ultra-high Frequency Current on *B. typhosus* Agglutinin and Complement

E. E. ECKER AND M. O'NEAL

*The Institute of Pathology, Western Reserve University, Cleveland, O.*

THERE appeared in the literature as early as 1915 a controversy as to whether high fevers depress or destroy the agglutinins to *B. typhosus* in vaccinated individuals. Tidy<sup>1</sup> observed that febrile conditions apparently remove the agglutinins to *B. typhosus* from the blood after inoculation. Dreyer,<sup>2</sup> however, disagreed with this view. After further observations Tidy<sup>3</sup> again stated that in his opinion marked hyperpyrexia of whatever cause, in inoculated individuals, tends to destroy the agglutinins. Dreyer<sup>4</sup> then showed that in a series of 108 cases inoculated within a year, various febrile diseases failed to change the agglutination titer materially. Tidy<sup>5</sup> pointed out that Dreyer had no controls for his series and was, therefore, not justified in his conclusions. Up to the present, so far as we know, no further work has been contributed to clear up the controversy.

An opportunity presented itself to produce hyperpyrexia in experimental animals by means of placing them in the electromagnetic field created by a high frequency vacuum tube oscillator. By means of the hyperpyrexias thus induced, it was possible to study further the effects of high fevers on agglutinins and complement.

Although Schereschewsky<sup>6</sup> had thought the band of frequency of such a current between 20,000,000 and 80,000,000 cycles per second exerts a specific lethal effect on living tissue cells, it has been shown by Knudson and Schaible,<sup>7</sup> Jacobson and Hosoi,<sup>8</sup> Bischoff, Ullmann, Hill and Long,<sup>9</sup> and Mortimer<sup>10</sup> that the physiological and morphological changes produced by exposure to an ultra-high frequency current are no different from those produced by hyperpyrexia induced by any other method. Christie and Loomis<sup>11</sup> have shown that the effects produced on animals can be fully explained on the basis of the heat generated by the induced high frequency current. They could find no evidence to support the theory that certain wave lengths have a specific action on living cells.

TABLE I  
AGGLUTININS (TYPE EXAMPLE RABBIT 1958)

Animal	Date 1932	Time Heated Hrs.	Temperature Degrees C.	Hb. Per cent	R. B. C.	Agglutinin Titers

" "	5- 9	2	42.1	65	5,350,000	1:40
" "	5-10		37.4	68	4,825,000	0

The physiological effects of the alternating current can be profoundly changed by variations in frequency (D'Arsonval<sup>12</sup>). As the frequency of alternation is increased, a point is reached where stimulation no longer occurs, and the subject feels only a sensation of warmth and prickling of the skin. As the frequency is still further increased, the prickling sensation disappears until at  $10^6$  cycles per second, heat production is the only effect which can be demonstrated. At frequencies below 50,000,000 cycles per second the effect of these radiations on animals is proportional to the intensity of the electromagnetic field.<sup>11</sup> Using this type of machine, then, we can test the effect of hyperpyrexia without fear of any complicating side effects.

#### METHOD OF EXPERIMENT

A high frequency vacuum tube oscillator, manufactured by the General Electric Co. was used to induce the fever. The animals were placed in a well ventilated wooden box in the electromagnetic field created by two metal electrodes between which the current alternated at  $10^7$  cycles per second. The temperature of the animals was recorded by a rectal thermometer, care being taken to insert the bulb well into the rectum in order to get true readings. The temperature was controlled by regulating the distance between the electrodes.

Five rabbits were tested for the thermal effect on agglutinins to *B. typhosus*. One month before the hyperpyrexia was produced these animals were prepared by subcutaneous inoculations, (4) at 5-day intervals, of 0.5 and 1.0 c.c. of killed typhoid vaccine containing 1,500,000,000 organisms per c.c. Routine agglutinations were done before and after heating, using the Kinyoun strain of *B. typhosus*.

The serum of 3 rabbits in 1:2 dilution, and 9 guinea pigs in 1:30 dilution were titrated before and after heating for complement.

In each animal, also, red blood cell counts and hemoglobin determinations (Sahli method) were made both before and after heating, in order to determine the effect of radiation on blood volume.

#### RESULTS OF EXPERIMENT

Five rabbits were heated for lengths of time varying from 30 minutes to 4½ hours. The temperature obtained was 40.2° to 43° C., a change of 2.1°–4.9° C. from the normal. In each case, after heating, the agglutination titer was lowered, greater depression being observed after the longer periods of heating. The titer of the agglutinins had returned to normal within 24 hours to 1 week in every case except 1, in which the titer kept decreasing in spite of the administration of an additional 1 c.c. of vaccine. In 1 instance, in which the temperature had reached 43° C., the animal did not survive and the terminal agglutination titer rose to 1:1,280, whereas the original titer had been 1:320. The blood volume was concentrated little or not at all by the extreme hyperpyrexias, as shown by the hemoglobin and total red cells, the latter being very slightly changed except in the fatal case in which both were markedly increased.

Nine guinea pigs were heated from 30 minutes to 3½ hours. Temperatures of 40.0° to 42.8° C. were obtained representing a rise of 2.8° to 6.2° C. from the normal. In each case the complement was depressed during the first heating. In 2 cases the complement decreased as the temperature returned to normal, only to be again depressed by a second heating. In 3 cases the complement was restimulated by subsequent heatings. As in the other animals, it was found that there was little or no change in the blood volume except in the fatal case in which it was decreased as shown by the increased hemoglobin and total red cells.

Three rabbits (Table II) were heated from 1½ to 2 hours. The temperatures reached were 40.1° to 43.1° C. a rise of 1.6° to 3.9° C. from the normal. Complement was decreased during the hyperpyrexia in all but 1 case (1958) in which it was stimulated. In 2 cases,

TABLE II  
COMPLEMENT (TYPE EXAMPLE GUINEA PIG I)

Animal	Date 1932	Time Heated Hrs.	Temperature Degrees C.	Hb. Per cent	R. B. C.	Complement 1:30 Complete Hemolysis in
Guinea pig 1	3- 2		35.3	85	4,510,000	1:145
" " "	3- 2	2	41.0	75	4,500,000	1:125
" " "	3- 3		36.8	75	3,840,000	1:125
" " "	3-29		36.0	85	5,600,000	1:100

" " "	3-30			68	3,500,000	1:100

(TYPE EXAMPLE RABBIT 1958)

Complement 1:2

Rabbit 1958	Date	Time Heated Hrs.	Temperature Degrees C.	Hb. Per cent	R. B. C.	Complement 1:2
Rabbit 1958	4-25		38.5	67	5,150,000	1:110
" "	4-25	2½	40.0	72	5,220,000	1:200
" "	4-26		38.1	68	3,120,000	1:250
" "	5- 4		37.5			1:100
" "	5- 9		37.5	72	5,300,000	1:200
" "	5- 9	2	42.1	65	5,350,000	1:100
" "	5-10		37.4	68	4,825,000	1:100

in which complement was depressed during the fever, it rose as the temperature returned to normal. Blood volume was very slightly changed as evidenced by hemoglobin and total red cell counts.

These results are important in the routine diagnosis of typhoid fever when often, during the hyperpyrexia, blood is withdrawn for a Widal test and a low titer (1:60) found. Such cases have come to our notice and stimulated this work.

## SUMMARY

1. Hyperpyrexia was induced in 9 guinea pigs and 10 rabbits by means of a high frequency electric current. Temperatures of  $40.5^{\circ}$ – $43.1^{\circ}$  C. were obtained. Temperatures of  $42^{\circ}$  C. or over, if maintained for any length of time, were lethal.

2. The hyperpyrexia so induced depressed, but did not entirely destroy, inoculation agglutinins to *B. typhosus*. The amount of depression was roughly proportional to the length of time of heating and the degree of temperature obtained.

3. The inoculation agglutinins returned to their original titer within 24 hours to 1 week, except in 1 fatal case in which there was a terminal stimulation beyond the original titer.

4. Complement was usually depressed on first heating, but on a second was stimulated. In no case was it completely or permanently destroyed.

5. Hyperpyrexia has no permanent effect on inoculation agglutinins. If they are depressed during the time of fever, they soon return to normal.

NOTE: We wish to thank Dr. C. J. Wiggers for the use of the high frequency vacuum tube oscillator and Dr. H. A. Blair for his advice on the use of the machine.

## Safety Education

THE progress of safety education in the schools of the United States will be traced by William John Cooper, U. S. Commissioner of Education, at the Twenty-First Annual Safety Congress and Exposition, October 3 to 7 in Washington. While automobile accidents involving adults have been increasing in recent years, accidents involving children of school age have been drastically reduced, and this is largely the result of teaching habits of play and work to children in the school.—*Public Safety* (National Safety Council), 6, 9:10 (Sept.), 1932.

# Observations and Studies on Silicosis by Diatomaceous Silica<sup>\*</sup>

ROBERT T. LEGGE, M.D., and ESTHER ROSENCRANTZ, M.D.

*Department of Hygiene; and Department of Medicine;  
University of California Medical School, San Francisco, Calif.*

BECAUSE of the excessive morbidity and high mortality from silicosis and tuberculosis, the South African Government created, in 1926 at Johannesburg, the Miners' Phthisis Medical Bureau. It is due to the researches of this bureau that we owe our modern knowledge of silica dust diseases.

At the Rand there are employed nearly 200,000 miners—European and native. These men work in quartzite which contains from 86 to 96 per cent of silica. As there is such a wealth of material for scientific investigation it was possible for investigators to determine the causation and the pathology of the disease. Much credit is due to Drs. W. Watkins-Pitchford and Mavrogordato for their statistical studies and for the classification of the different stages of the disease. This was determined from physical examinations, chemical and roentgen-ray examinations, and autopsy findings. They demonstrated that silica of 0.5 to 5  $\mu$  gained access to the lung structure by the endothelial wandering cells, lining the air vesicles. These cells engulf the particles and carry them into the lymph channels where they become encapsulated and ultimately fibrosed in the lung structure.<sup>1</sup>

A characteristic change in simple silicosis is the production of a pigment about the silica particles that have accumulated about lymph spaces, blood vessels, and the finer bronchial structures. Ultimately many of these particles and pigments become surrounded and infiltrated with new areas of fibrosis and nodules. In tuberculosis with silicosis there is always an excess of pigment at the immediate site where the specific lesions are nodulated and have undergone fibrosis.

It has been practically demonstrated by all investigators that silica is the only dangerous dust that causes definite pathology in the lung tissues with the exception of bacteria, and that pulmonary silicosis is probably caused by the colloidal action of hydrated silica

<sup>\*</sup> Read at the Third Annual Meeting of the Western Branch American Public Health Association at Denver, Colo., June 11, 1932.

formed from the minute particles of dust disseminated through the lobes of the lung. With the etiology and pathology understood, investigations were carried on to determine the various stages and progress of the symptoms of the disease and the interpretation of the roentgen-ray examinations during these stages. At the same time this brought about careful medical supervision and methods of controlling dust hazards as preventive measures.<sup>2</sup>

There is evidence to show that the activity of colloidal silica in the lungs may be prevented by protecting the silica dust with a substance known to coagulate colloidal silica.<sup>3</sup> This explains why the morbidity and mortality are lessened and the length of time increased before the "effective period" occurs, as has been shown in certain abrasive industries where clay is present with the silica and in coal mines where shale is present.

These important observations should receive careful consideration by mine operators. They should determine the physical and chemical structure of the material mined or quarried and a careful analysis should be made of the percentage of silica and other contents that make up the substance. One may theoretically be able to determine the length of time it requires the different stages of silicosis and tuberculosis to ensue by the amount of silica present and to draw conclusions when the inert substances that have a coagulating effect on the particles of silica in the pulmonary structures are absent or present in smaller percentages.

Experimentally it may prove beneficial to introduce in quartz mines inert clays to obviate the silica hazards even after such preventive measures as mechanically driven ventilating exhausts, dust traps, and wet processes of drilling have been installed.

Furthermore, the careful studies of investigators in this country and Great Britain since the pioneer researches at the Rand enriched the literature by statistics, methods of diagnosis, technic and interpretation of roentgen-ray examinations; they have also brought about legal classifications for compensation and methods for prevention. Clinical experiences, mortality statistics, and post-mortem examinations are convincing proofs that silica is dangerous, as it produces a lung pathology that is a favorable site for the ravages of the tubercle bacillus. The effect of coal on miners and cement dust on the workers exposed tends to chronic bronchitis and pneumonia, and occasionally tuberculosis.

At the Rand two clinical forms of silicosis are recognized: simple silicosis and silicosis with tuberculosis. In simple silicosis, a condition arises which is associated with the presence of numerous

small inert nodules of dense fibrous tissues scattered symmetrically and uniformly throughout the parenchyma of both lungs. When these nodules are abundant and closely aggregated, upon the slightest exertion the worker experiences shortness of breath. The intensity of this symptom is in proportion to the amount of exertion. The outstanding physical signs are limited expansion, slight dullness in the upper part of the chest, harsh and high pitched inspiration, and a tendency to obesity.

Later, in the second stage, the nodules become larger, are aggregated into masses, and tuberculosis is superimposed. The clinical features are increased limitation of chest expansion, loss of weight, marked dyspnea, cough, expectoration, pleuritic pains, and much disability with cachexia. Of the advanced cases, 78 per cent were observed to be of this type and all among the native workers due to their marked susceptibility to the tubercle bacillus. The onset in all cases was simple silicosis. From silica dust contact to the recognition and appearance of silicosis is about  $10\frac{1}{4}$  years. This is known as the "Effective Period."

In the past decade many studies have been published on silicosis and other diseases caused by dusty trades. Extensive investigations were made on the lung pathology by the introduction of silica subcutaneously into the tissues and by silica inhalation. New methods of determination of air dustiness have been devised. The cardinal symptoms of the disease have been determined by all the modern methods.

Many contributions have been added to the knowledge of pneumoconiosis due to silica and many special fields have been investigated—"Miners' Consumption Among Zinc Miners in Missouri"; "Problem of Dust Phthisis in Granite Stone Industry"; "Exposure to Calcium Dust in Cement Plants"; "Dust Inhalation by Hematite Miners"; "Silicosis Among Rock Drillers, Blasters, and Excavators in New York City"; "Effects of Coal Dust on Miners"; "Dust Hazards in the Abrasive Industry," etc., etc.

In California about 350 miles south of San Francisco, in Santa Barbara County, there exists the largest and purest diatomaceous deposit probably in the world. This is in the Coast Range Mountains, at an altitude of 400 to 600 feet above sea level and 10 miles inland. A large firm is now utilizing this substance for commercial purposes. This deposit is composed of fossilized diatoms and microscopic unicellular marine algae with a silicified cell wall which when dry contains about 85 per cent silica. Due to its remarkably diversified properties it is extensively used in various important industries.

The natural substance looks like a fine deep cream colored powder. It is the greatest nonconductor of heat known and bricks made from it are used in building furnaces.

Due to its lightness, porosity, whiteness, and clarifying qualities it is also used extensively as a filtering agent. Also, due to its high silica content, it is a permanent element in concrete and does not affect the time of setting. It is also used extensively in the abrasive industries.

Being an entirely new enterprise, the operators were obliged to devise and construct special machinery for transportation, refining, and manufacturing. The machinery has not yet been perfected, although improvements in construction are constantly being evolved. Due to these imperfections and the operative methods a great deal of dust is disseminated in the atmosphere in certain working zones and constantly surrounds the habitations of the workers, as the plant operates night and day.

This material is transported from the mine by aerial trams to the cyclones and grinders in the mill, in preparation for the dryers and other machinery. The menace is due to vast clouds of dust which escape and endanger the immediate workers and are also disseminated by the prevailing winds over the district where the employees reside. At the mill the bag house is very dusty, as well as the packing quarters where the product is sacked; also where bricks are made by being sawed.

In the mine the ventilation is excellent and dust is not a factor on account of the high percentage of moisture in the product. The only places in the mine where the dust is pronounced are at the "glory hole" discharge terminals where the drag lines operate, and where the dumps are released to fill the trams.

The workers are selected Mexican laborers who have been given a physical examination by the company's physician before being employed. These people, being primarily Indian, have the highest tuberculosis mortality rate in the United States. One hundred and eight employees were given a roentgen-ray examination of their chests; the films were interpreted; and their social and medical histories taken, by the technical staff of the Bureau of Tuberculosis of the California State Board of Health. The films were rechecked by a roentgenologist at the University of California Medical School and the chest physical examinations made by the two authors, both of the University of California. The dust content estimations were made by the U. S. Bureau of Mines; the industrial hygienic survey, and recommendations were conducted by Dr. Legge.

The 108 men selected were graded as follows: employed less than 1 year; 1 to 2 years; 2 to 5 years; 5 years or more; the purpose being to determine for statistical purposes the possible time and degree required to affect the worker.

The primary motive of the study was to determine for the California Tuberculosis Association whether the hazard was definitely instrumental in increasing the county's tuberculous incidence, also to make a preliminary study as to the degree of silicosis found by physical and roentgen-ray examination.

The ages of the Mexican laborers studied ranged from 19 to 56 years. Pneumoconiosis due to silica of various degrees was found present in 81, or in 68.5 per cent of the cases. It is readily observed in Table I that the disease is a very slow growing process and advances with the years of employment.

TABLE I

	Groups					Total
	I	II	III	IV		
	Years employed:					
	0-1	1-2	2-5	5 or more		
Very early pneumoconiosis.....	0	0	8	7	15	
Early pneumoconiosis . . . . .	6	12	11	16	45	
Moderately advanced pneumoconiosis.....	0	2	4	9	15	
Advanced pneumoconiosis . . . . .	0	0	1	5	6	

It is noted that the predominating form of the disease is in the early stage, 60 men showing early pneumoconiosis, whereas 15 were in the moderately advanced stage and only 6 in the advanced stage.

TABLE II

	Years employed:				Total
	Less than 1 year	1 to 2 yrs.	2 to 5 yrs	5 yrs or more	
<i>General Appearance:</i>					
Good . . . . .	13	16	33	37	99
Fair . . . . .	2	3	2	4	11
Emaciated . . . . .		2		6	8
<i>Clubbing of Fingers:</i>					
None . . . . .	5	3	15	9	32
Slight . . . . .	9	16	18	32	75
Moderate . . . . .	1	1	1	5	8
Marked . . . . .		1	1	1	3
<i>Recommendations:</i>					
Hospital care . . . . .				1	1
Change of work . . . . .	1		2	2	5
Re-examine 3 months . . . . .	1	5	8	14	28
Re-examine 6 months . . . . .	6	6	14	19	45
Re-examine 1 year . . . . .	7	9	12	8	36
No recommendations . . . . .		1		3	4

The outstanding features revealed by the physical examination was the splendid condition of the men. We found 99, or 84.0 per

cent, in a good state; 11, or 9.3 per cent fair; and only 8, or 6.77 per cent, poor. The physical signs were strikingly few. Limited expansion and a change in the percussion note depending upon the extent of the lung involvement, were the main signs in the chest. In 86, or 72.9 per cent, of the cases there were clubbed fingers in various degrees of development, depending upon the number of years of labor in the mine. *This is the most outstanding physical sign and also the earliest to develop.* During the first year of employment two-thirds of the cases already had clubbed fingers.

The company maintains a splendid village center with hospital, recreation activities, school, etc., and were very coöperative to ameliorate any hazards that are jeopardizing the health and safety of their employees. It is hoped that another survey may be made in the near future to follow up the preliminary investigation. The following recommendations, based on the findings, were suggested:

#### RECOMMENDATIONS

1. *Employment*—No person having bronchitis, asthma, tuberculosis, or cardiac disease should be employed. The selected workmen should have a recorded history of former employment and diseases; also a complete physical examination with an X-ray film of the chest, and every year thereafter the X-ray should be repeated. This ruling should apply to the officers as well as to the laborers.

2. *Clinic*—A chest specialist should hold a clinic every 3 months at the mine, the X-ray having been taken previously by the company's doctor. By examining the workers in groups of 125, the entire plant would thus have chest examinations by the end of the year. Those needing reëxaminations or observation could report at the next clinic.

3. *Rest*—There should be 1 day's rest in 7. The present work day should be of shorter hours. Workers should alternate from dusty to non-dusty employment.

4. *Family*—The women and children of the workers should be examined once a year for the reason that the Mexican has a lower immunity to tuberculosis and it would be well to know if there is tuberculosis in the family.

5. *Medical*—The company's hospital should be in charge of a well-trained physician who is capable of making a thorough physical and X-ray examination of the chest, keeping careful records, and making sanitary and safety plant inspections regularly.

6. *Mechanical*—Suitable machinery and transportation methods should be developed in order to prevent dust dissemination in the atmosphere. Mechanical exhausts, wet processes, isolation of dusty departments, and control drafts, as well as individual respirators, should be installed and be constantly a part of the plant.

# Adult Health Education

WALTER H. BROWN, M.D., F.A.P.H.A.

*Professor of Hygiene and Physical Education, Stanford University.  
Palo Alto, Calif.*

SHORTLY after the war, H. G. Wells made the rather startling statement that "the world must choose between education and catastrophe." These words scarcely aroused a ripple of interest. Those of us who pondered on them at all, thought he was referring to the education of children. As a matter of fact, he was talking about the adult generations. He was convinced that our stupendous blunder of identifying education with schooling and limiting that schooling to youth, could not continue if our civilization were to survive. The social, economic, and political events of the past 3 years seem to indicate the correctness of his opinion.

"It is not the education of children that can save the world from destruction; it is the education of adults. It is the adult who must be released from his narrow mindedness, his prejudices, his outworn customs, and his obsolete habits."<sup>1</sup> On every hand we have abundant evidence of the truth of this statement. If solutions are to be found for the vital problems upon which depend the survival of our present form of civilization, we must devise ways to educate or reëducate the adult. All this applies with peculiar force to the major health problems in which we are particularly interested.

It requires no argument to convince this group of the abundance of vital health problems which are literally crying for solution. Further, we all know that when we analyze one of these problems, in every case we give a prominent and important place in our proposed solution to what we call "education," and in these more modern days, "health education." Our discussion of adult health education, then, calls for a closer examination of what we mean by this term, and how it has become the newest shrine before which large numbers of public health workers now worship. Perhaps this analysis will also aid us in a wiser planning of our efforts to influence the attitudes and actions of the adult generation.

We have always considered the proper task of education to be the

---

<sup>1</sup> Read at the Third Annual Meeting of the Western Branch American Public Health Association at Denver, Colo., June 9, 1932.

teaching of children. The school was invented for the purpose of providing help to the community in connection with certain needs of community life. It was natural for health workers to turn to the schools, when they sought to solve health problems by education. It had become a common method used by groups interested in the solution of social problems. Many of our earliest courses of instruction in hygiene and physiology were made compulsory by state laws promoted by an organized group interested primarily in the control of the use of alcohol and tobacco.

The first step in the evolution of our modern health education programs in schools came from a different quarter. An alliance of the physician, the health officer, the educator, and the health propagandist aroused a widespread interest in the responsibility of the schools for the health of its pupils. This has led to a gradual acceptance of health as an important objective of education. Slowly but surely, we are developing sound courses in health instruction, improved methods of health supervision, and properly trained and experienced personnel to conduct them.

The results of these health education programs are difficult to measure by our usual statistical methods. There seems to be no doubt, however, that they can and do definitely raise the level of the health intelligence and health practices of the students. We are concerned here with a consideration only of the elements entering into effective health education of children as a basis for evaluating and planning adult health education. For the educational principles underlying sound procedure will be alike for both age groups.

If you analyze any successful effective plan of health education, you will find it is always based upon sound scientific facts, it has proper provision for arousing and maintaining interest, and secures the voluntary, willing participation of the pupils. This results, even in a child, in a determined and long continued effort to train his powers of observation and thinking as a guide to his decisions in matters of health. While it is true that this result is not attained in all the pupils, it is surprising what a large number of children develop health ideals coupled with health knowledge in such a way as to put their elders to shame with their health wisdom. The weakest link in our health chain is found in the adult generation.

Our next big job is to devise and promote sound methods of adult health education. We need more than an emotional aspiration of health workers for better health as a basis for this task. It will necessitate our junking the pet theory that education is synonymous with schooling and terminates at the door of the school or college. We will

be compelled to realize that while we have neglected this important matter the field has been largely preëmpted by the quack, the charlatan, and commercial parasites who find the average adult an easy prey. It will be necessary for us to find ways to overcome the inertia or opposition of the average individual, who claims his ancient right to be ignorant, careless, thoughtless, and prejudiced about matters pertaining to health. We must seek as diligently for ways to arouse his interest as we have done for that of the child, and having gotten it—give it something substantial to feed upon. In fact, adequate health education will require skilful adaptation of our best educational methods to the attitudes and psychology peculiar to the adult.

Many of you protest that you have not neglected the field of health education. You ask: have we not given health lectures, shown health movies, published health literature, broadcast health talks, run health exhibits, promoted campaigns against various diseases, conducted prenatal clinics and mothers' classes? Yes—you have—and in many cases with remarkable skill and enthusiasm. They are all important and useful, as are many other efforts to reach the adult; but taken alone or even in combination they do not constitute "health education" in the sense we need to define it under modern conditions.

Really to educate an adult with reference to health you must do more than indoctrinate him by health propaganda—though that has its place. You cannot be satisfied merely to ladle out health information to him—though heaven knows he needs that. You must fight a terrific battle against indifference and stupidity among people who have demonstrated over and over again that they can be roused and controlled by catchwords and appealed to through simple emotions.

Our task then is to explore the principles and methods that have proved successful in producing real educational results in children and adapt them, if possible, to the adult level. The first step in such an endeavor would seem to be a critical review of the present methods of approach being used to influence the adult in his decisions on matters of health. These may be discussed for convenience under the head of health information, health propaganda, and health education.

A large part of the time and efforts of all health workers is devoted to giving out health information either to individuals or groups. This is a fundamental service without which the progress of our health programs would be delayed if not stopped. Consequently, an analysis of its place in an adult health education program is in order.

The first requisite of sound health information is that it be based upon facts. So-called health facts are frequently neither true nor important. The time has come for us to look a little closer at factual

bases of our health information. Armstrong,<sup>2</sup> in a recent article in the JOURNAL, proposes a current appraisal of health data:

- I. Assured Health Facts:
  - A. Those universally and practically applicable
  - B. Those theoretically sound but limited in application because of the imperfections in available methods or for other reasons
- II. Near Facts:
  - A. Those about which there is a growing certainty, though as yet no absolute scientific assurance
  - B. Those once generally accepted but about which there is an increasing element of doubt
- III. Assured Health Fallacies

He goes a step further by suggesting that we have some facts that can be labelled Grade A facts. Included here we find such items as the established fundamentals of diet and our exact knowledge about the prevention and cure of certain communicable diseases. Under Grade B—near facts—we discover many of the very appealing ones which we believe to be true, but cannot actually prove: "Drink 4, 6 or 8 glasses of water a day; sleep 8 hours a day; brush your teeth twice a day to prevent caries," and many more which we feel are in the right direction though they need verification. It seems unnecessary to dwell upon the health fallacies—properly classified as Grade C—and not to be used by careful, reputable health workers.

It seems obvious that sound health information has an indispensable rôle to play in any plan of adult health education. That legitimate health workers are bound by their own professional standards to evaluate carefully the truth of their factual materials, and to use these accurately and honestly, even though their competitors, the quacks and commercial parasites, are bound by no such standards.

#### HEALTH PROPAGANDA

The word propaganda has fallen on evil days. Its early history finds it describing efforts to convert men to the religious life. The war changed this meaning to represent everything that was horrible and terrifying. Notwithstanding its shady reputation, I want to speak a good word for propaganda, especially health propaganda, for it represents an organized effort for spreading the doctrine of health and the principles that govern it. Of course, in approving it, I am referring to the propaganda based upon facts, not on fallacy, fancy, or fraud.

True or wholesome propaganda is an effort to take the certified facts that science has shown will influence the levels of health and use

them accurately and honestly to influence the individual or group without any hope of personal gain. Whenever and wherever this standard is met by the individual health worker or the organization, we have one of our most useful and necessary tools.

To be true or wholesome the facts must be certified and the use must be accurate and honest. As an example, it is a certified fact that vaccination will prevent smallpox, and consequently we are justified in using every fair means to convince the individual that vaccination is desirable. It would be neither accurate nor honest to say that the procedure of vaccination never results in infection in the individual. A large part of the educational efforts of our official and voluntary health agencies may fairly be classified under the head of wholesome propaganda.

False propaganda is based upon facts or near facts improperly or dishonestly used, or upon definite fallacies. The propagandist is motivated by either commercial or selfish aims. It is in this field that we find one of the most potent influences against both individual and community health. We need not discuss the systems of propaganda based upon definite fallacies. They are dangerous and they present some of our most difficult public health problems.

We should be more concerned, however, about the enormous increase in the types of propaganda either based upon facts or near facts. Skilfully and adroitly used by well paid and frequently well trained individuals, they are pouring a golden stream into the pockets of commercial organizations and individuals. The most superficial reading of the advertising pages of our most highly circulated magazines yields an interesting crop. Health can be very simply attained by eating so much of this or that. Pictures of attractive young ladies, flanked by the inevitable "leading medical authority" (conveniently foreign) give what Armstrong calls "an aura of reality to what is mostly fiction."

And now comes the radio. One of the most deadly sources of dangerous propaganda is the uncontrolled broadcast. The commercial ones are bad enough, heaven knows, but they fade into insignificance beside the quack. It is high time that some active steps were taken to confine the statements of these individuals to as near the truth as are the labels on foods and drugs.

#### HEALTH EDUCATION

This term has surely come to be something to be conjured with. It seems to mean different things to different people. Many groups claim it as their own, such as educators, school physicians, public

health nurses, nutritionists, and physical educators. Lately one hears it applied to the publicity activities of numerous commercial concerns. The explanation of this condition probably lies in the fact that a part of the process is being mistaken for the whole. We will use it here to describe all of the methods, processes, and activities which, taken together, so arouse the interest of the individual in matters of health that he is willing to make a serious effort not only to acquire health knowledge but also to establish health habits and attitudes based upon such knowledge.

When we refer to adult health education we are referring to this broader conception, for we are convinced that if we are really to educate the adult in health we must do more than expose him to health propaganda and feed him health information. In fact *we* cannot "educate" him, he must educate himself, for we agree with Buttrick, when he says: "Education is a voluntary process. In the very nature of the idea, one must educate himself." Consequently, the first step in an adult health education program is to provide methods of arousing the interest of the individual in health. This is frequently well done through the popular lecture, newspapers and magazines, movies and radio. This must be followed systematically by the second step—the provision for adequate facilities for making easily available sound scientific health information. This may mean proper health literature adapted to the needs and curiosity of the interested individual. Or it may mean the encouragement of the person to attempt some more systematic study either in a group or through independent investigation. Or again, it may call for individual medical or health guidance.

To summarize the essential points: true adult health education is an active, not a passive, process; it is based upon a maintained intellectual interest; it results in seeking adequate health knowledge; and its outcome is an individual who is capable of exercising intelligent discriminating judgment in matters pertaining to personal and community health.

If asked whether adults can be interested in this type of program, I would answer that in other fields of endeavor they have been, wherever and whenever adequate leadership has been forthcoming. Recall the lyceums, university extension courses, Chautauqua movement, forums, and study courses of various organizations in this country, not to mention the workers' education movement abroad.

Yes, adults can be interested in health education if we are ready to furnish the leadership and to organize a program that will compete successfully for the interest of the individual. This means not only sound planning but also high grade promotion of the idea. The oppor-

tunity for the promotion of public health through adult health education has attractive possibilities. I am convinced that we have men and women who are capable of exercising the leadership. This brings us to our final question of how such a program can be organized and conducted in a community.

### THE PROGRAM

Our first step is to decide what we consider should be the minimum essentials for health education in any community. While the extent and completeness of this program will be governed by local conditions, every community should have well organized and unified facilities for:

1. *Health propaganda*—These facilities should include a well organized method for making available health lectures by qualified persons, health exhibit materials, reliable radio broadcasts on health, and facilities for preparing copy and securing proper health publicity. Skilful health propaganda is our best method of arousing the individual interest.

2. *Health information*—There should be provision in every community for making available reliable health information to the public. This may be done through the health department or in special programs through a voluntary agency. An excellent example of dissemination of medical information and guidance is the work of King's County Medical Society in Brooklyn, N. Y.

In addition to health information for the public, it would be profitable for us to provide easily accessible sources of more technical information for the professional health worker of the community.

3. *Health instruction*—Every community with a well considered community health plan should see to it that facilities for proper health instruction are available for all ages. This should include:

*Schools*—While the actual program of health instruction in the schools is the job of the school administrator, it is a legitimate function of the group interested in community health to be sure that the schools have a satisfactory course of instruction properly integrated with the community health program.

*Adult classes*—In this field should be included facilities for class instruction in special subjects covering even a wider range than we now provide so successfully on various special topics.

*Study courses*—The provision of study courses for use by organized groups, such as Parent-Teacher Associations, Women's Clubs, and we hope some day men's organizations, is one of the devices for adult health education that has proved its value, when well planned and properly conducted. In addition, it is becoming increasingly desirable to provide guidance to individuals who can be interested in an independent study of health problems through reading courses.

You will note you are familiar, and for bringing them to the attention of our health workers will come closer

Questions are all methods with which you are using. My purpose is for organization and unified objectives if we base our

health education programs upon the health needs of the whole community rather than the individual projects of our own organization.

As a definite application of this idea, it is suggested that we should organize a community council on health education, with representatives from the official health departments, educational system, voluntary health agencies, and professional groups such as physicians and dentists. This council would be an advisory and coördinating body. It might very well begin its activities by taking the following steps:

1. *Survey*—A systematic study of all the health education activities and programs in the community, and an analysis of this material with an estimate of its completeness and effectiveness as to its meeting fully the community needs.

2. *Community Program of Health Education*—With the survey as a basis, planning of a unified community health education program, including all age groups, this program to be adopted after adequate group discussion. The responsibility for the promotion of its individual projects to be allocated to the organization best equipped to carry it out effectively.

There is nothing original in this device for coördination of health activities. It has demonstrated its usefulness in many other fields. We believe that it will function in the field of health education. It is merely suggested as one method of securing a systematic, integrated plan of health education.

In conclusion, then, we may not be compelled to choose between "education and catastrophe," but we must choose between health education and failure of our public health programs. Health education of adults as well as children must become a well planned procedure based upon sound educational principles. Further, the success of our health plans as a whole will be conditioned by how clearly all of the health workers in the community see the necessity for, and are ready to participate in, a well considered, unified health education program.

## SELLING SEWAGE TREATMENT ON FACTS — NOT FANCY

IN these times of curtailed outlet for industrial enterprise, individuals and corporations are looking, with a covetous eye, at the field of municipal undertakings and improvements. This will be even more true if funds for construction of public works and utilities become available from the Reconstruction Finance Corporation. Included in this program will be the construction or extension of sewerage and sewage treatment works.

Corporations having a staff of engineers and chemists, while casting about for new business and endeavoring to make the fullest possible use of existing facilities and personnel, in some instances have become attracted to one of the frequent municipal undertakings—sewage treatment and waste disposal. They see in sewage treatment a relatively undeveloped field with an apparent ample opportunity for the production of less complex, more practical and less costly processes than are now employed. As to the treatment of industrial wastes, there seems to be an even greater field in view. Some promoters have an idea of developing self-supporting features with by-product recovery from the treatment and disposal of the polluting materials at the minimum cost and without regard to attempted recoveries of

health nurses, nutritionists, and physical educators. Lately one hears it applied to the publicity activities of numerous commercial concerns. The explanation of this condition probably lies in the fact that a part of the process is being mistaken for the whole. We will use it here to describe all of the methods, processes, and activities which, taken together, so arouse the interest of the individual in matters of health that he is willing to make a serious effort not only to acquire health knowledge but also to establish health habits and attitudes based upon such knowledge.

When we refer to adult health education we are referring to this broader conception, for we are convinced that if we are really to educate the adult in health we must do more than expose him to health propaganda and feed him health information. In fact *we* cannot "educate" him, he must educate himself, for we agree with Buttrick, when he says: "Education is a voluntary process. In the very nature of the idea, one must educate himself." Consequently, the first step in an adult health education program is to provide methods of arousing the interest of the individual in health. This is frequently well done through the popular lecture, newspapers and magazines, movies and radio. This must be followed systematically by the second step—the provision for adequate facilities for making easily available sound scientific health information. This may mean proper health literature adapted to the needs and curiosity of the interested individual. Or it may mean the encouragement of the person to attempt some more systematic study either in a group or through independent investigation. Or again, it may call for individual medical or health guidance.

To summarize the essential points: true adult health education is an active, not a passive, process; it is based upon a maintained intellectual interest; it results in seeking adequate health knowledge; and its outcome is an individual who is capable of exercising intelligent discriminating judgment in matters pertaining to personal and community health.

If asked whether adults can be interested in this type of program, I would answer that in other fields of endeavor they have been, wherever and whenever adequate leadership has been forthcoming. Recall the lyceums, university extension courses, Chautauqua movement, forums, and study courses of various organizations in this country, not to mention the workers' education movement abroad.

Yes, adults can be interested in health education if we are ready to furnish the leadership and to organize a program that will compete successfully for the interest of the individual. This means not only sound planning but also high grade promotion of the idea. The oppor-

tunity for the promotion of public health through adult health education has attractive possibilities. I am convinced that we have men and women who are capable of exercising the leadership. This brings us to our final question of how such a program can be organized and conducted in a community.

### THE PROGRAM

Our first step is to decide what we consider should be the minimum essentials for health education in any community. While the extent and completeness of this program will be governed by local conditions, every community should have well organized and unified facilities for:

1. *Health propaganda*—These facilities should include a well organized method for making available health lectures by qualified persons, health exhibit materials, reliable radio broadcasts on health, and facilities for preparing copy and securing proper health publicity. Skilful health propaganda is our best method of arousing the individual interest.

2. *Health information*—There should be provision in every community for making available reliable health information to the public. This may be done through the health department or in special programs through a voluntary agency. An excellent example of dissemination of medical information and guidance is the work of King's County Medical Society in Brooklyn, N. Y.

In addition to health information for the public, it would be profitable for us to provide easily accessible sources of more technical information for the professional health worker of the community.

3. *Health instruction*—Every community with a well considered community health plan should see to it that facilities for proper health instruction are available for all ages. This should include:

*Schools*—While the actual program of health instruction in the schools is the job of the school administrator, it is a legitimate function of the group interested in community health to be sure that the schools have a satisfactory course of instruction properly integrated with the community health program.

*Adult classes*—In this field should be included facilities for class instruction in special subjects covering even a wider range than we now provide so successfully on various special topics.

*Study courses*—The provision of study courses for use by organized groups, such as Parent-Teacher Associations, Women's Clubs, and we hope some day men's organizations, is one of the devices for adult health education that has proved its value, when well planned and properly conducted. In addition, it is becoming increasingly desirable to provide guidance to individuals who can be interested in an independent study of health problems through reading courses.

You will note that these suggestions are all methods with which you are familiar, and all or part of which you are using. My purpose for bringing them together is to make a plea for organization and unification of our health education programs. It seems to me that we will come closer to attaining our health objectives if we base our

health education programs upon the health needs of the whole community rather than the individual projects of our own organization.

As a definite application of this idea, it is suggested that we should organize a community council on health education, with representatives from the official health departments, educational system, voluntary health agencies, and professional groups such as physicians and dentists. This council would be an advisory and coördinating body. It might very well begin its activities by taking the following steps:

1. *Survey*—A systematic study of all the health education activities and programs in the community, and an analysis of this material with an estimate of its completeness and effectiveness as to its meeting fully the community needs.

2. *Community Program of Health Education*—With the survey as a basis, planning of a unified community health education program, including all age groups, this program to be adopted after adequate group discussion. The responsibility for the promotion of its individual projects to be allocated to the organization best equipped to carry it out effectively.

There is nothing original in this device for coördination of health activities. It has demonstrated its usefulness in many other fields. We believe that it will function in the field of health education. It is merely suggested as one method of securing a systematic, integrated plan of health education.

In conclusion, then, we may not be compelled to choose between "education and catastrophe," but we must choose between health education and failure of our public health programs. Health education of adults as well as children must become a well planned procedure based upon sound educational principles. Further, the success of our health plans as a whole will be conditioned by how clearly all of the health workers in the community see the necessity for, and are ready to participate in, a well considered, unified health education program.

## SELLING SEWAGE TREATMENT ON FACTS — NOT FANCY

IN these times of curtailed outlet for industrial enterprise, individuals and corporations are looking, with a covetous eye, at the field of municipal undertakings and improvements. This will be even more true if funds for construction of public works and utilities become available from the Reconstruction Finance Corporation. Included in this program will be the construction or extension of sewerage and sewage treatment works.

Corporations having a staff of engineers and chemists, while casting about for new business and endeavoring to make the fullest possible use of existing facilities and personnel, in some instances have become attracted to one of the frequent municipal undertakings—sewage treatment and waste disposal. They see in sewage treatment a relatively undeveloped field with an apparent ample opportunity for the production of less complex, more practical and less costly processes than are now employed. As to the treatment of industrial wastes, there seems to be an even greater field in view. Some promoters have an idea of developing self-supporting features with by-product recovery from the treatment and disposal of the polluting materials at the minimum cost and without regard to attempted recoveries of

by-products. Still others have no interest in process development, but see only an outlet for mechanical units which may be applicable in one or several existing or proposed processes.

All or any of the proposed or projected schemes can work to the good of sanitation development by giving impetus to the movement toward stream cleansing, now well under way in America. If this new undertaking, strange to individuals and corporations uninitiated in the basic principles of waste treatment and requirements in stream pollution correction, is adequately guided by experienced engineers and chemists qualified to advise in such matters, the way will be smoother, and progress sounder and more rapid in the long run. Such advisers or consultants must be competent to understand what is required in the matter of degree of purification in given instances; wherein a particular process may be adequate or inadequate; wherein it will be able to produce results alone or may require amplification to the extent of some secondary treatment, biological or chemical. So far there has not appeared a simple and economical process which can be considered ample under all circumstances of stream condition and waste treatment and it does not seem probable that a single process will answer. There is need for greater flexibility than is economically procurable from a single process and it will be necessary for those developing new and unproved schemes to consider this feature carefully.

In marketing new schemes, or old ones which have been improved and amplified, it will be necessary to "sell" on *fact* and not on *fancy*. The process which produces an effluent pleasing to the eye, without odor nuisance, and void of elements dangerous to human or animal health, will answer the requirements in a great majority of instances, but there will be others wherein the residual but invisible organic matter in such an effluent may be more than the stream can assimilate during the critical periods when flows are deficient. During such periods amplification of the otherwise satisfactory treatment may prove essential.

Mechanical or chemical engineers thoroughly competent to develop industrial processes, and already proved successful in their field, may find themselves poorly understood by the sanitary engineer or the chemist of experience in stream pollution matters. These same men with the assistance of the experienced sanitarian, working in close coöperation and acting as an interpreter of the language and viewpoint of the state and national health departments or stream pollution commissions, may produce a process of waste treatment superior to any yet developed.

Producing and marketing novel processes and equipment for sewage treatment has not proved and will not prove as simple as the producers may expect, and much confusion will result unless these producers or promoters market the process on a sound technical basis with the aid of staff members or counsel qualified to evaluate pollution conditions and definitely assure economically sound performances commensurate with requirements. Disregard of such principles in marketing new sewage treatment processes by attempting to "sell" by other and less sound methods has not met with any real and material success in the past nor will it now.

### THE WASHINGTON MEETING

WE wish to call attention to the 61st Annual Meeting of the American Public Health Association, the time for which is rapidly approaching. Washington is the place, a city always full of interest from many different standpoints. Everyone wishes to go to Washington at least once a year, and this occasion will present an opportunity of attending a scientific meeting which is full of interest as well as of visiting the Capital City of our country. Other countries have been hit by the depression, but the attendance at scientific meetings has been good in spite of this, and we wish now and here to urge everyone who can possibly do so to be with us.

The preliminary program shows that there is certainly no depression in the production of scientific work, for which we have every reason to be thankful. While the program discusses matters of general interest on topics in which all are interested, in Washington there will be several special features. There will be five speakers on mental hygiene, all of whom are well known specialists. The prevention of diphtheria, the consideration of toxoids as against toxin-antitoxin, the standardization of serums, studies of the value of serums in the treatment of poliomyelitis, tests for anti-pneumococcic serum, and many other items will be considered. The program of the Laboratory Section is especially complete, and there are few matters of interest to laboratory workers which are not included in it.

There will be one paper on the relation of heart disease and public health. We have had a great deal of material on throat infections followed by rheumatism, on the tonsils as routes of infection and production of valvular disease of the heart; but very little has been written upon heart disease as a public health problem directly.

The Section on Food and Nutrition is also well filled, covering

many items of special interest. A new feature has been added—the Public Health Ten Star Final, in which specialists will give a symposium on the current work of the ten sections now composing our Association. The names of those taking part in this symposium assure us of its value and interest.

Another feature will be the Institute on Health Education, the purpose of which is to provide instruction in the content and methodology of health education to a limited number of persons actively engaged in this work.

At the same time that our meeting is going on, a number of other closely related societies, in which many of our members hold membership, will hold sessions, such as the American Association of School Physicians, International Society of Medical Health Officers, Conference of State Sanitary Engineers, State Laboratory Directors' Conference, Association of Women in Public Health, Delta Omega, American Social Hygiene Association, etc. Several of these have met coincidentally with us for several years; but this year we have in addition the National Shell Fisheries Association and Oyster Growers and Dealers Association of North America, with a program which includes many interesting items beginning with the biology of the oyster, and ending with the hygienic supervision of the shellfish business.

It scarcely seems necessary to mention the many attractions of the City of Washington, with its museums, art galleries, the wonderful Congressional Library, governmental departments, the National Institute of Health, etc. It was hoped that the new buildings of the National Institute of Health would be open in time for this meeting, but this expectation will not be fulfilled. However, the contracts have been let and the administration building is under way.

Once again we wish to urge all members to make every effort to be present so as to make our 61st gathering, the first annual meeting held in Washington since 1918, a great success.

# ASSOCIATION NEWS

WORD has been received that President Hoover will honor the American Public Health Association by appearing before it at some occasion during the sessions of the Sixty-first Annual Meeting, if it is at all possible for him to do so. No one will doubt that Mr. Hoover's wishes in the matter are to bring a greeting to the Association. His absorbing interest in public health is too well known to need comment.

Mr. Hoover has been an Honorary Fellow of the American Public Health Association since 1917. He is Honorary President of the American Child Health Association and President of the American National Red Cross.

## NEW MEMBERS

*The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.*

### *Health Officers Section*

P. P. Causey, M.D., Courtland, Va., Southampton County Health Officer  
Frederick E. Clark, M.D., 316 New York Ave., Ogdensburg, N. Y., Health Officer  
Charles W. Decker, M.D., 116 Temple St., Los Angeles, Calif., Health Officer  
Theodore F. Foster, M.D., Board of Health, West Hartford, Conn., Superintendent of Health  
Jacques P. Godard, 10 rue des Archers, Lyon, France, Public Health Administration (Assoc.)  
Burdge P. MacLean, M.D., 33 Fairview St., Huntington, N. Y., Deputy Commissioner of Health  
Harry E. Ransom, M.D., City Health Dept., Des Moines, Ia., Health Commissioner  
Elwin F. Reamer, M.D., P. O. Box 1598, Modesto, Calif., Stanislaus County Health Officer  
J. W. Scudder, M.D., Calhoun, Ky., Director, McLean County Health Dept.

### *Laboratory Section*

Elmer J. Pearson, Box 1304, Minot, N. D., Bacteriologist, Minot Branch Laboratory

### *Public Health Engineering Section*

Ben L. Grimes, Jr., Box 881, San Angelo, Tex., District Engineer, State Dept. of Health

Robert H. Murray, C.E., Dept. of Public Health, Regina, Sask., Director, Division of Sanitation  
E. C. Sams, 614 E. Burton St., Murfreesboro, Tenn., Sanitary Inspector, Rutherford County Health Dept.

### *Industrial Hygiene Section*

Elston L. Belknap, M.D., 231 W. Wisconsin Ave., Milwaukee, Wis., Medical Director, Globe Union Manufacturing Co.  
Ernest T. Manning, M.D., Rm. 1224, Telephone Bldg., Omaha, Nebr., Health Director, Northwestern Bell Telephone Company

### *Child Hygiene Section*

Arthur S. Lamb, M.D., McGill University, Montreal, P. Que., Director, Dept. of Physical Education  
Mary E. Morse, M.D., Wine Ave., Hyattsville, Md. (Assoc.)  
Elizabeth C. Wells, M.D., 513 W. Main St., Riverhead, N. Y., School Physician

### *Public Health Nursing Section*

Leah M. Blaisdell, R.N., State Dept. of Health, Albany, N. Y., Assistant to the Extension Secretary, Staff Education Program for Public Health Nurses of New York State  
Florence D. Fischer, R.N., Washington County Health Dept., Jonesboro, Tenn., Public Health Nurse

Betty M. Pennington, R.N., Obion County Health Unit, Union City, Tenn., Public Health Nurse

Vincent Saccardi, 4815 17th St., N. W., Washington, D. C. (Assoc.)

Gertrude G. Shay, R.N., Metropolitan Life Insurance Company, Jersey City, N. J., Local Supervisor, Nursing Service

Emily M. Smith, R.N., Washington County Health Unit, Jonesboro, Tenn., Public Health Nurse

Mary E. Walker, 1601 Bolton St., Baltimore, Md., Superintendent, Instructive Visiting Nurse Association

#### *Epidemiology Section*

Gaston Melo Andrade, Depto de Salubridad, Paseo de la Reforma y Calzada de Tacubaya, Mexico, D.F., Mex., Chief, Public Health Dept.

Burke Diefendorf, M.D., Copake, N. Y., District State Health Officer

Charles H. Halliday, M.D., 3505 N. Calvert St., Baltimore, Md., Epidemiologist, State Dept. of Health

#### *Unaffiliated*

C. T. Conway, U. S. Standard Products Co., Merchandise Mart, Chicago, Ill. (Assoc.)

J. O. Dean, M.D., Lawrenceville, Va., U. S. Public Health Service

#### ADDITIONAL APPLICANTS FOR FELLOWSHIP \*

HEALTH OFFICERS SECTION—John D. Monroe, M.D., Pontiac, Mich., Vladimir K. Volk, M.D., Dr.P.H., Pontiac, Mich.

LABORATORY SECTION—James Gibbard, M.Sc., Ottawa, Ont., Canada, Edward L. Miloslavich, M.D., Milwaukee, Wis.

VITAL STATISTICS SECTION—Lloyd R. Gates, D.P.H., Ann Arbor, Mich.

#### DECEASED MEMBERS

Lafayette Higgins, Des Moines, Ia., Elected Member 1913, Fellow 1922

Mathilde S. Kuhlman, R.N., Albany, N. Y., Elected Member 1920, Fellow 1927

Davis Furman, M.D., Greenville, S. C., Elected Member 1929

O'Neill Kane, M.D., Kane, Pa., Elected Member 1928

Cassius T. Lesan, M.D., Mount Ayr, Ia., Elected Member 1929

\* See JOURNAL, Aug., p. 847, and Sept., p. 947.

Members and subscribers are requested to send notification of any change of address to the office of the Association as promptly as possible.

# PUBLIC HEALTH ADMINISTRATION

Baltimore Health and Hospital Survey—A comprehensive survey report of the health and hospital service in Baltimore for the year 1931 has been prepared by Surgeon Joseph W. Mountin of the U. S. Public Health Service. The survey staff functioned under a large Citizens Committee and sub-committees concerned particularly with executive problems, general administration, communicable diseases, maternity and infancy, hygiene of the school child, general sanitation, and hospitals.

The city health department budget for 1932, of \$719,336, is 20.3 per cent below that of the preceding year. The proportional reduction in personnel and activities is about the same. The sum expended by the health department represents only a small part of the total expenditure of the city and—

It would seem that Baltimore might very well devote a larger percentage of its tax dollar to health purposes, since with advancing science health becomes more and more a purchasable commodity.

Experience has demonstrated that a health program becomes a more potent influence when activities are localized. Certain functions, notably child hygiene and nursing, are being developed on a neighborhood basis, but there should be administrative decentralization as well. A limited number of sub-offices should be established at strategic points throughout the city for the distribution of existing services.

Regarding personnel, it is considered desirable as the future policy to employ full-time trained public health workers for the administrative and regulatory functions of the health department and to draw on the practicing physicians with special training when filling clinical positions requiring only part-time service. The formation of a Council of

Health Agencies is suggested. On this Council would be represented the various official and nonofficial organizations engaged in public health and related activities. It could serve as a forum for the discussion of projects affecting two or more member agencies; it would be a medium for interpreting public health work to the people, and a means for organizing public support of the work. In addition, it is believed that the position of the health commissioner would be strengthened were he to assemble a group of consultants to whom he could turn for advice on particular problems.

This carefully prepared document charts a course for future development of public health work in the city along lines which seem sound in the light of modern knowledge. Many of the principles set forth should prove of practical interest to many health administrators.

I. V. H.

Ontario County, N. Y.—In a survey conducted in June, 1930, there was summarized an outline of the existing health facilities of Ontario County, official and voluntary, town, village, and county, with a recommendation that there should be only one health agency in the county. Surprisingly it is shown that a modern consolidated full-time health organization with well trained personnel will cost the taxpayers less than the obsolete township system now in effect. The principal stumbling block to progress seems to be the 14 town and village health officers who are dependent in part, at least, upon their meager stipends.

Ontario not only blazed the trail in the pioneer days of New York State

when it included within its boundary all the territory west of Albany, but it was the first New York county to boast, in 1906, of a county public health laboratory. Its tuberculosis hospital has been in operation since 1910. It is one of two counties in the state which have taken advantage of the state law permitting the organization of a county school hygiene district.

With a population of 54,239 in 1930 a preliminary estimate of budget is placed at \$76,760 to include a health officer and assistant, 16 nurses including a chief, half time of a tuberculosis officer (who will also be superintendent of the sanatorium), 3 inspectors, a clerk, a stenographer, \$16,000 for travel, \$7,000 for laboratory, \$1,000 for office expense and \$4,000 for miscellaneous expense.—Allen W. Freeman, Survey of Health Organization, New York State Charities Aid Association, *Pub. 198*, 1932.

**Administrative Practice in Scarlet Fever**—As of 1930, a detailed examination has been made of the isolation and quarantine requirements for scarlet fever in 44 of the larger cities of the United States. In many instances the regulations are decidedly confused and often indefinite. There is also a lack of uniformity in principles involved. There should be prepared minimal re-

strictions compatible with safeguarding the public health. There is need for clarification of terms and better understanding of the technics involved. Also, uniform terminology would permit progress through comparison of experiences. Evaluation of the bacteriological methods now in vogue, the effect on the communicability of scarlet fever, of degrees in type of disease, age of patient, and geographical and seasonal variations are only a few of the relationships to be determined.—George B. Darling and John E. Gordon, *American Administrative Practice in the Control of Scarlet Fever. J. Prev. Med.*, 6:185 (May), 1932.

**Poliomyelitis in San Francisco**—In 1930, the California district experienced its most extensive outbreak of poliomyelitis. Beginning in June, 1930, the epidemic continued through the following March. There were reported 245 local and 50 non-local cases, and 32 deaths. Although no part of the city was free from the disease, it was found that the prevalence was directly proportional to the density of population. Males were affected more frequently than females and 75 per cent of the males were hospitalized.—J. C. Geiger and J. P. Gray, *Statistical Study of Poliomyelitis in San Francisco in 1930, J. Prev. Med.*, 6:145 (May), 1932.

# LABORATORY

## THE GREENBURG-SMITH IMPINGER SAMPLING APPARATUS FOR DUSTS, FUMES, SMOKE, AND GASES<sup>1</sup>

LEONARD GREENBURG, M.D., PH.D., F.A.P.H.A.

*Department of Public Health, Yale School of Medicine, New Haven, Conn.*

ONE of the most important of present-day problems in the field of industrial hygiene is that concerned with the effects of the dust which the worker is forced to inspire by virtue of his occupational exposure. In the study of such problems it is essential to obtain accurate information concerning the amount, size and nature of the dust suspended in the air of the workroom.

The Greenburg-Smith impinger apparatus was designed by the writer and G. W. Smith for the purpose of sampling aerial dust.<sup>2</sup> This instrument was found to be superior to the others tested at the U. S. Bureau of Mines during the

course of a detailed study of the sampling efficiencies of the various instruments available for this purpose.<sup>3</sup> When operating at a sampling rate of 1 cu. ft. per minute this instrument possesses high catching efficiency when tested against dust or smokes. A representative sample may therefore be obtained in a relatively brief sampling period. With this instrument any suitable liquid may be used as the sampling medium which may then be studied microscopically or analyzed chemically.

On the completion of the laboratory studies this instrument was placed in field use. For the past 9 years it has

TOP VIEW  
FIGURE I—ELECTRICALLY DRIVEN SUCTION APPARATUS  
[1077]

been used with a high degree of success for the sampling of normal outdoor air, of various industrial dusts, of lead dust, coal dust, of chromic acid mist, of lead fumes, and of sulphur dioxide. The present note is presented at this time so that persons requiring an instrument for the sampling of fumes, gases, smoke or dusts may be familiar with this device.

#### THE IMPINGER APPARATUS

The impinger apparatus consists essentially of two portions: First, a source of sufficient suction to draw the air to be sampled through the sampling device; and second, the sampling device or impinger itself, which consists of a container and the impinger tube and plate. As a source of suction we have

made use of an electrically driven and a compressed air driven apparatus.

#### ELECTRIC SUCTION APPARATUS

The electrically driven suction apparatus (see Figures I, II and III) is designed to be used in places where electrical energy is available. The motor is a series-wound, single-phase 60-cycle, alternating-current motor of 1/15 h.p., rated at 1.6 amperes, at 110 volts, with a speed of 1,800 r.p.m. and operates on either alternating or direct current. It is geared to a positive pressure blower of the Roots type by means of a set of gears having a 1 to 3 ratio. In order to minimize noise, the smaller of these gear wheels is made of fiber, the larger being metal. The blower is rated at 4 cu. ft. of free air per minute at a speed of 600 r.p.m., and is used as the source of suction. Wired in series with the electric motor is a 98-ohm, 1.6-ampere variable sliding rheostat used for speed control of the motor. By employing such a rheostat, 110 or 200 volts may be used. To the intake or suction side of the blower is attached a 1/4" malleable-iron elbow fitting provided with two inlets. To one

FIGURE II—ELECTRICALLY DRIVEN SUCTION APPARATUS

FIGURE III—ELECTRICALLY DRIVEN SUCTION APPARATUS

of the inlets, a  $\frac{1}{4}$ " brass needle valve by-pass is attached. The second inlet of the elbow is connected to a constriction type glass flowmeter or vacuum gauge for measuring the rate of air flow. The inlet side of the flowmeter is connected to the sampling flask by means of a piece of non-collapsible rubber tubing, of any suitable length.

The electric motor, blower, rheostat, electric plug, and switch are all assembled on a metal plate 9" by 14" and  $\frac{1}{8}$ " in thickness, and this plate is in turn firmly screwed to the base of the carrying case. The carrying case is made of  $\frac{1}{2}$ " quartered oak, the outside dimensions being  $10\frac{1}{2}$ " by  $15\frac{1}{2}$ " by  $9\frac{1}{4}$ ". The weight of the apparatus is 45 lb.

#### COMPRESSED-AIR SUCTION APPARATUS

In many industrial establishments, mines, and quarries, compressed air is readily available. By means of a very simple device called an ejector, the compressed air may be converted into suction which is then used for the sampling of the atmospheric dust (Figure IV).

The inlet (compressed-air) side of the ejector is provided with an adapter so that the usual  $\frac{1}{4}$ " nipple, as ordinarily used for small compressed air lines, may readily be attached. To the suction side of the ejector, a  $\frac{1}{4}$ " iron tee is attached, and to the outstanding leg of this tee a second tee connection is fitted. To the outstanding leg of the second tee, an ordinary vacuum gauge,

FIGURE IV—COMPRESSED AIR DRIVEN SUCTION APPARATUS

for measuring the rate of air flow, is connected, while to the other leg there is attached an ordinary  $\frac{1}{4}$ " pipe union. Finally, to the unoccupied end of this union is fastened a short pipe nipple over which a suitable length of rubber tubing is attached.

Between the two halves of the pipe union there is placed a Monel metal disk approximately 1.5 mm. in thickness, pierced at its center by a circular orifice  $\frac{7}{64}$ " in diameter. By employing such an orifice plate, it is possible to obtain a gauge reading approximately double that obtainable without the use of this device.\*

The ejector type of instrument weighs approximately  $3\frac{1}{2}$  lb.

#### IMPINGER TUBE AND FLASK

The impinger tube is constructed of a piece of heavy wall pyrex glass tubing 13 mm. in outside diameter, approximately 325 mm. in length (this length is optional), tapered at its lower end to a stream-line form with a terminal orifice of 2.3 mm. diameter. The impinger plate is of pyrex glass approximately 25 mm. in diameter, 3 mm. in thickness and is fastened to the

impinger tube by means of three glass supporting rods about 9 cm. in length, so that the distance between the orifice of the tube and the plate is 5 mm. (Figure V).

There is wide latitude in the choice of the sampling flask which may be used in conjunction with the impinger tube. In fact, we have employed three different flasks during the course of our studies. The choice is governed by the

FIGURE V—IMPINGER TUBE

\* We are indebted to Theodore Hatch, Harvard School of Public Health, for the design for this orifice plate attachment.

requirements of the particular task at hand.

At the present time we are using a flask made in the form of a tube sealed at the lower end, 300 mm. in length and 50 mm. in diameter, provided with a 2-hole rubber stopper (Figure VI). The outlet tube from the sampling cylinder is connected to the source of suction by means of a convenient length of non-collapsible rubber tubing.

Whether bottle flask or cylinder is used, sufficient liquid should be kept in the container during use to cover the impinger plate to a depth of approximately 3 cm. In the cylinder type of flask 100 c.c. are sufficient to accomplish this, whereas if the Erlenmeyer type of flask is used, 250 c.c. are required. A baffle plate on the exhaust tube, as shown in Figure VI, is of value for the prevention of entrainment of water from the sampling flask.

FIGURE VI—GLASS SAMPLING CYLINDER AND COMPLETE IMPINGER

#### METHOD OF SAMPLING—CALIBRATION OF THE IMPINGER APPARATUS

It is necessary to calibrate the vacuum gauge or flow meter air measuring device of the impinger apparatus so that one may control the rate of air sampling. For calibration, the apparatus should be assembled in a manner precisely similar to that employed in field sampling, but with the outlet tube of an accurate 5-light, dry, test gas meter attached to the inlet of the impinger apparatus. A calibration curve is then obtained, showing the relationship between rates of air flow, as measured by the gas meter during observed intervals of time, and the readings on the scale of the flow meter or vacuum gauge. The scale reading corresponding to 1 cu. ft. per minute may then be ascertained from the calibration curve.

#### SAMPLING FLUID

The choice of the sampling fluid is dependent on the analyses contemplated. In studies of non-toxic indus-

trial dusts we employ distilled water. In the case of those dusts not easily wetted by water, such as coal dust, a mixture of 25 per cent alcohol and 75 per cent water has been employed with excellent results. The alcohol increases the wetting power of the solution and at the same time greatly reduces the solubility of mineral dusts in water. It is important that the sampling fluid itself be comparatively free from suspended matter.

For the sampling of  $\text{SO}_2$ , Smith and Friis<sup>4</sup> have employed 0.1 normal sodium hydroxide, and for the sampling of chromic acid mists, Bloomfield and Blum<sup>5</sup> employed normal sodium hydroxide.

In the preparation of the apparatus and solutions for field use the degree of care and the precautions usually exercised in quantitative chemical work should be adhered to.

#### SAMPLING AND ANALYSIS OF DUST SAMPLES

In the field the apparatus is assembled and set up in a suitable place, the proper

amount of sampling fluid is placed in a flask and the impinger tube is placed in position. The flask, with its tube, is then placed in the chosen sampling position and the suction is started. It is important to note that sampling should be carried out at a rate of 1 cu. ft. per minute since the dust catching efficiency of the instrument is decreased when a lesser sampling rate is used. After a suitable period of time the instrument is shut down, the impinger tube is rinsed with distilled water, the rinsings being added to the original sampling fluid, and the flask stoppered for transport to the laboratory.

In the laboratory the dust suspensions are filtered through a 325-mesh screen and then diluted so that the number of particles in the microscope field is equal to approximately 50 to 75. Two or more 1-c.c. portions are placed in Sedgwick-Rafter cells for counting. The microscope is of the ordinary type employing a 7.5 x eyepiece and a 16 mm. objective. A Whipple disc eyepiece micrometer is placed in the microscope eyepiece and the microscope tube length is adjusted so that the side of the ruling

in the eyepiece is 1 mm. in length. As a source of illumination we employ the ordinary type of microscope lamp with the iris of the Abbé condenser system adjusted so as to provide a high degree of visibility. In making counts the microscope should be focused throughout the depth of the cell, since some particles may remain in suspension. It is, of course, necessary to make control dust counts on the sampling fluid.

NOTE: For a more complete description of the counting technic the reader is referred to the contribution in the *Public Health Reports* of March 18, 1932.

## JOINT STATEMENT OF AMERICAN WATER WORKS ASSOCIATION AND AMERICAN PUBLIC HEALTH ASSOCIATION ON PROCEDURE FOR ISSUING STANDARD METHODS FOR THE EXAMINATION OF WATER AND SEWAGE

THE importance of a standard laboratory technic for examination of water and sewage is recognized by all. The mechanics of reaching agreement upon such standard methods, however, is not so generally understood or accepted. Varied interests, conflicting opinions, prejudices of one kind or another, and the sheer mechanical difficulty of reconciliation of many groups

have retarded increasingly in recent years the prompt issuance of a manual acceptable to the field at large. Some of this delay has been due to frank differences of opinion regarding choice of technic, but a much greater part has had its origin in administrative obstacles to agreement, to lack of opportunity for direct personal contact for exchange of ideas by members of the responsible

committees, and by research committees attempting to function as executive agents.

The increasing dissatisfaction of many workers in the field with the current standards and the unfortunate departure of many important laboratories from the use of *Standard Methods* made it essential for both the American Public Health Association and the American Water Works Association to find some procedure for facilitating the prompt issuance of *Standard Methods*, commensurate with the current acceptance of new or modified procedures. A review of the situation by interested groups disclosed quite clearly that the most fruitful direction for bringing about this desideratum was in the creation of a small, compact, editorial committee, distinct from the investigating committees, whose sole function should be the crystallization of current thought and data into prompt publication for use. The basis for the operations of this committee naturally remains in the research groups of the respective associations, but the mechanics of formulation of technic was regarded as more likely to be efficiently performed by a small group than by large, discrete, and loosely knit research committees. Their functions likewise were thought to be quite distinct.

In the light of these conclusions, it appears advisable to inform the membership of the American Public Health Association and the American Water Works Association as to the changes which have been made in personnel for and methods of preparation of new editions of *Standard Methods for the Examination of Water and Sewage*.

By an agreement which became effective in 1925, this manual of methods, which had formerly been prepared by the American Public Health Association alone, became the product of the coöperative activity of the two associations. Since that time certain adminis-

trative reorganization has taken place or became effective in both associations.

In the American Public Health Association, the Committee on Research and Standards has become the clearing house through which proposals for research projects are routed and to which the Association as a whole looks for coördination and direction of all research work. In the American Water Works Association the Committee on Water Works Practice occupies a similar position and performs a similar function.

While it is doubtless unnecessary to point out to most workers in this field, it may be worth while, for the benefit of a few who may not have thought the subject through, to recall that the establishment of such associational clearing houses of research and group activity is becoming more widespread and has its highest development in certain national organizations most conspicuous for their activity and excellent performance.

The chairmen of the two associations' committees, after a review of the progress that was being made under the 1925 joint editorial agreement, have obtained the approval of their respective boards of directors to a reorganization of the groups engaged in editing *Standard Methods*.

This reorganization consists briefly in the appointment of a joint Editorial Committee of six—three from each association—who have organized and have been functioning as a single committee since the Memphis Convention of the American Water Works Association.

The members of the Joint Editorial Committee are:

*American Public Health Association*

John F. Norton, Detroit, Mich.

A. M. Buswell, Urbana, Ill.

L. M. Wachter, Albany, N. Y.

*American Water Works Association*

Wellington Donaldson, New York, N. Y.

Paul Hansen, Chicago, Ill.

*Chairman:* Harry E. Jordan, Indianapolis, Ind.

This joint committee is empowered to carry on all the negotiations incidental to the preparation of new and revised editions from time to time, to the point of detailed and complete formulation of manuscript. After the completion of such manuscript, the material is to be submitted to the two parent associations for the detailed ratification which those associations may determine upon in their own practice. Funds have been allotted for the work of the committee.

In the American Water Works Association the manuscript will be submitted to the Chairman of the Committee on Water Works Practice who will, after satisfying himself and his committee, through whatever channels appear wise, as to the character of the material submitted, approve it and forward it to the Secretary of the association. A like copy of the manuscript will be forwarded to the Chairman of the American Public Health Association Committee on Research and Standards. He will obtain the approval of the manuscript by his committee, after similar intra-association review, and forward the material to the Secretary of the A.P.H.A.

The approved manuscript is then to be printed and bound under the direction of the General Secretary of the A.P.H.A. An annual accounting for expenses and receipts connected with the preparation and sale of *Standard Methods* will be made by the secretaries of the two associations.

It is planned that such research on methods as may be organized in the A.W.W.A. shall take the form of appointments by the Chairman of the Water Purification Division with the advice of the Joint Editorial Committee and the approval of the Committee on Water Works Practice. Whenever it becomes evident to the Editorial Committee that a revision of an item of current procedure is needed or whenever the members of the Water Purification

Division in regular meeting by their action indicate a similar conclusion, a research or revision group may be organized to study the particular subject. Such research groups are to be appointed for 1 year only, and will be expected to make a report at a regular meeting of the division. If, in the opinion of the Joint Editorial Committee, it is evident that the study has not reached a status that justifies a change in current procedure, the research group may be re-appointed for another year with such additions to or changes in personnel as may be indicated. The policy of a definitely limited term of appointment of research groups is adopted as a means of accelerating results rather than of restraining the activities of any individual or group.

On the other hand, the Joint Editorial Committee is charged with the responsibility of contact with all research wherever organized as it may relate to the subject matter of *Standard Methods*. Whenever it becomes evident that the validity of research by any person or group is amply demonstrated, it is expected that a proper change will be made in the text of *Standard Methods*.

While the standing of the text on *Standard Methods for the Examination of Water and Sewage* has rested in the past upon its adaptability to the determination of the sanitary and chemical characteristics of natural waters or those only slightly changed from their natural condition, it has become evident that the text should include data concerning determinations on highly modified waters for steam boiler purposes.

The Joint Editorial Committee is already in agreement with the Chairman of the A.W.W.A. Committee on Boiler Feed Water Studies, that whenever his committee is in agreement as to the technic of such determinations, the Joint Editorial Committee will expand *Standard Methods* to contain the material.

The Joint Editorial Committee will endeavor to keep adequately informed as to the activities of water quality research committees in the National Electric Light Association, American Gas Association, American Railway Engineering Association, American Society for Testing Materials, and other organizations of similar scope.

Its coöperation with the Committee of the American Chemical Society and the Society of American Bacteriologists is thoroughly established. Contact has already been established with the Laboratory Methods Coördination Committee of the Great Lakes and Ohio River Board of State Sanitary Engineers. It is anticipated that, whenever the Federation of Sewage Works Associations organizes research studies

on methods applicable to the sewage field, the fullest harmony will exist and that whenever new or modified methods are developed, they will be readily accepted by the Joint Editorial Committee for inclusion in *Standard Methods*.

A new edition of *Standard Methods* will issue this autumn, and it is anticipated that, with the coöperation of the various research committees, future revisions will appear as promptly as the extent of revised material justifies the expense of a new edition.

ABEL WOLMAN, for the Committee on Research and Standards—A.P.H.A.

MALCOLM PIRNIE, for the Committee on Water Works Practice—A.W.W.A.

## VITAL STATISTICS

**Vital Statistics for West Virginia, 1931**—There were 39,325 births reported in West Virginia during 1931. The birth rate was 22.4 per 1,000 population, by far the lowest rate since 1925, when West Virginia was admitted to the registration area. At that time the birth rate was 27.7. Of the total number of births in the state, 94.7 per cent were among the white population and 5.3 per cent among the colored. The stillbirth rate, 38.8 per 1,000 live births, was higher than in 1930 when it was 37.1.

In 1931 there were 17,620 deaths from all causes, 600 less than in 1930, the death rate in 1931 being 10.0 per 1,000 population as compared with 10.5 in 1930. Among the notifiable diseases, typhoid fever (showing a death rate of 12.7 per 100,000 in 1931), diphtheria (9.3), influenza (34.0), and poliomyelitis (1.3) showed increases over the 1930 rates, while measles (2.3), scarlet fever (1.7), whooping cough (7.5), and

tuberculosis (60.1) showed declines in 1931 over 1930.

Among the principle causes of death, the mortality from cancer (all forms) decreased from 59.7 per 100,000 population in 1930 to 58.6 in 1931. The fact that there was a decrease instead of an increase in cancer mortality is noteworthy, especially in view of the strikingly low rate which West Virginia showed in 1930.

Diseases of the heart declined from 117.0 in 1930 to 111.3 in 1931 and diseases of the circulatory system from 146.3 to 130.4 for the same years respectively. A marked decline is shown for diarrhea and enteritis under 2 years, the rate for 1931 being 54.6 as compared with 70.3 for the previous year. The maternal mortality rate was 5.2 per 1,000 live births. In 1930, it was 5.6. The largest percentage of puerperal deaths was due to septicemia. Apoplexy (68.3 in 1931), diseases of the nervous system (95.3), alcoholism (5.1),

nephritis (64.9), and syphilis (9.5) showed increases over the rates for 1930.

The infant mortality rate for the state as a whole, during 1931, was 77.2 per 1,000 live births, as compared with a rate of 80.9 in 1930. Five counties, Clay, Tucker, Jefferson, Mineral, and Wirt, showed infant mortality rates of over 100.—*West Virginia Quart. Bull.*, 19:4-6 (July), 1932.

**Accidental Deaths Drop 2,000 in 1931**—Accidents in the United States during 1931 caused approximately 97,000 deaths and 10,000,000 non-fatal injuries.

Staggering as the figures sound, the fatality total is 2,000 less than in 1930 and 1,000 less than in 1929. The reduction from 1930 is accounted for by a net decrease of 1,500 industrial deaths and of 1,000 home fatalities. Motor vehicle accidents caused 500 more deaths in 1931 than in the previous year. Incidentally, this reduction in the total accidental deaths is the first reduction that has been recorded since 1922. The death rate stood at 78.2 per 100,000 population in 1931, the lowest rate since 1925 when the rate was 75.7. The accident rate in the United States is still three times as high as that of Denmark, approximately twice that of Japan, and 50 per cent higher than that of France.

Steam railroads established an all-time safety record in 1931. There were fewer fatalities during the year than in any year since 1888, when the Interstate Commerce Commission's records begin. There were 5,099 deaths last year, compared with 5,481 in 1930.

Approximately 33,500 deaths occurred in motor vehicle accidents during 1931. This may be contrasted with 32,929 in 1930, 24,430 in 1926, and 13,939 in 1921. Of the 45 states reporting on motor vehicle deaths, 27 participated in the upward movement. Largest increases occurred in Nevada, Wyoming,

and Montana. Among the states showing declines, New Mexico and Arizona lead the list with drops of 35 and 14 per cent, respectively. Pennsylvania, Ohio, and Michigan, among the larger states, also had fewer deaths in 1931 than in the previous year. Based on the provisional figures, Nevada has the highest 1931 death rate, with California second. North Dakota has the lowest rate—15.5 per 100,000 population—followed closely by Mississippi, South Dakota, Oklahoma, and Louisiana.

Urban states (60 per cent or more city population) show the smallest increase in motor vehicle deaths, 1.4 per cent, from 1930 to 1931. Rural states (60 per cent or more rural population) show an increase of 1.6 per cent, whereas states between these extremes show the largest increase, 2.2 per cent.

The seriousness of the motor vehicle accident problem is emphasized by comparison with homicides and suicides. The latest available figures show that more than three times as many persons are killed by motor vehicles as meet death at the hands of criminals. This difference has developed during the past decade; the homicide rate has increased from 7.1 to 8.4 deaths per 100,000 population since 1920, whereas the motor vehicle death rate increased from 11.8 to 25.7—118 per cent.

Detailed information on 1930 accidental deaths indicates that school children are continuing the outstanding progress in safety that has been going on since 1924. The accidental death rate for persons of all ages increased from 69.6 in 1922 to 80.6 in 1930, an advance of 16 per cent. Among children between the ages of 5 and 14, however, the death rate was only 36.03 in 1930 compared with 40.08 in 1922, a decline of 11 per cent. The rate for children under 5 declined 5 per cent in the same period. The contrast is even more striking for deaths from automobile accidents. This rate for persons

of all ages advanced 98 per cent during this time while the rate for school children advanced only 4 per cent. For children under 5 there was an increase of 45 per cent.

Of the 30,000 deaths in homes in 1930, nearly 12,000 are charged to falls, and of these 8,000 were among persons 65 years of age or over. Burns and scalds are about half as important as falls, and the deaths from this cause are concentrated at the earlier ages, nearly one-half of all deaths occurring among children under 15.

The death rate from drowning in 1910 was 9.0 and reached a maximum of 10.2 in 1913. It then dropped to a low rate of 5.7 in 1920 and has since fluctuated considerably, the 1930 rate being 6.1. Firearms also cause a fair share of the public accidental deaths. The greatest hazards are to young men, about one-third of the annual total occurring in the age group 10 to 19 and another 20 per cent in the age group 20 to 29.

Deaths in aviation accidents increased to a new high total of 620 in 1930. Final Bureau figures are not yet available for 1931, but there is every indication that there was a decrease last year. In civil aviation accidents only, as reported by the Aeronautics Branch of the U. S. Department of Commerce, there was a decline from 529 deaths in 1930 to 439 in 1931. If a similar decline occurs for all aviation, the deaths will number slightly more than 500. On the basis of miles flown, scheduled air transport operations continue to show much greater safety than miscellaneous flying.—R. L. Forney, Accident Deaths Drop 2,000 in 1931, *National Safety News*, 26:34-38 (July), 1932.

**Preliminary Report on Marriage and Divorce for the United States, 1931**—The U. S. Bureau of the Census announces that, according to the returns received, there were 1,060,095 marriages performed in the United

States during the year 1931, as compared with 1,128,572 in 1930. These figures represent a decrease of 68,477 or 6.1 per cent. There was a decrease of 8.4 per cent from 1929 to 1930. During the year 1931, there were 183,695 divorces granted in the United States, as compared with 191,591 in 1930, representing a decrease of 7,896 or 4.1 per cent, as against a decrease of 4.9 per cent from 1929 to 1930. There were 4,338 marriages annulled in 1931, as compared with 4,370 in 1930.

The estimated population of continental United States on July 1, 1931, was 124,070,000, and on July 1, 1930, 123,191,000. On the basis of these estimates, the number of marriages per 1,000 of the population was 8.5 in 1931, as against 9.2 in 1930; and the number of divorces per 1,000 of the population was 1.49 in 1931, as against 1.56 in 1930.

While the net decrease in the number of marriages performed in the country as a whole was 6.1 per cent, the relative change in the different states ranged from a decrease of 49.7 per cent in Idaho to an increase of 25.1 per cent in Nevada.

Only 11 states reported increased marriage rates with percentages as follows—New Hampshire 7.6, South Dakota 7.8, Nebraska 7.6, Maryland 0.5, Virginia 6, West Virginia 2.4, South Carolina 1.5, Florida 1.1, Kentucky 9.7, Utah 1.6, and Nevada 25.1.

Of these, 8 adjoin states in which recent changes made in the marriage laws, require from 3 to 5 days to elapse between the application for a marriage license and the issuance of the same. South Dakota adjoins Iowa, change effective July 1, 1931; Minnesota, April 29, 1931; and Wyoming, June 1, 1931. Nebraska also adjoins Iowa and Wyoming. Virginia and South Carolina border North Carolina and Tennessee where restrictions became effective July 1, 1929. West Virginia is a neighbor to

Ohio where the change became effective July 23, 1931. Kentucky adjoins both Ohio and Tennessee. Utah borders Colorado, change effective September 1, 1931; Idaho, March 16, 1931, and Wyoming; while Nevada adjoins Idaho and California, where the change was made July 29, 1927. Of the remaining 3 states, Maryland has long been a Gretna Green for adjoining Delaware where restrictions have been in effect for some years and Florida borders Georgia where restrictions are in effect for persons under 21 years of age. New Hampshire, however, not only adjoins states where the 5 day interval must elapse but carries the same law on its statutes.

The changes in the various states as regards the number of divorces in 1931 as compared with the year 1930, ranged from a decrease of 26.4 per cent in Mississippi to an increase of 101.6 per cent in Nevada. Increased rates for divorces were reported in 11 other states, New Hampshire, Connecticut, New York, New Jersey, Wisconsin, North Dakota, South Dakota, Georgia, Kentucky, Wyoming, and Utah. The number of divorces granted in the District of Columbia more than doubled, due to increased court facilities. The rate was not computed, however, as the number reported for 1930 was less than 100.

In 1931, for the United States as a whole, 5.8 marriages for each divorce were reported, as against 5.9 in 1930. The District of Columbia and New York State, each having but one cause for absolute divorce, reported 24.7 and 22.4 marriages to each divorce, respectively, while the rates in the states ranged from 12.1 marriages to each divorce in Georgia to 1.5 marriages to each divorce in Nevada.—Dept. of Commerce, Bureau of the Census, Press Summary (July 18), 1932.

**Cancer in Australia**—The report of the Second Australian Cancer Confer-

ence held at Canberra in March, 1931, gives some details of the history and epidemiology of cancer in Australia which are not without interest. The total mortality from cancer in the Commonwealth has risen steadily from 34 in 1879 to 98 in 1929. In New South Wales, Victoria, and South Australia, statistics going back to 1859 are available. In 1859 the rates for the three countries were 14, 10, 10, respectively. There was a great jump in the next 10 years to 25, 27, 15 and in 1929 the rates had reached 95, 107, 109. In Western Australia the rate has risen from 4 in 1869 to 92 in 1929.

In the 19th century cancer was less common in Australia than it was in Europe, and it is still less common, though its acceleration has been more rapid and probably by the end of next year the Australian rate will be little if any below that of Britain, viz., 147. During the 10 years 1920–1929 the Commonwealth rate has increased from 84 to 98, not quite regularly. During this period no alteration of certification has taken place, nor has significant improvement of diagnosis occurred. On the other hand, treatment has improved, so that the incidence rate (which is unknown) must have increased more rapidly than the mortality rate.

In some sites, cancer has declined both absolutely and relatively to other sites. Cancer of the tongue in males is falling; in females it is increasing, but it is still so uncommon in the fair sex that even a continent cannot give a significant figure. Cancer of the womb is rising, but less rapidly than in other sites. Cancer of the anus and rectum doubled in males and increased 60 per cent in females between 1908 and 1929, while the disease in the whole digestive tract has risen from 25.2 to 51.4 in males and from 20.1 to 34.3 in females during the same period. Mortality from cancer of the skin is stationary as it is everywhere; probably incidence has increased

but treatment has improved to balance it.

Research in cancer is proceeding in Australia as it is elsewhere and much upon the same lines and with the same results. Experimental work on cancer is characterized not by failure but by confusions. Australian figures show that though "carcinoma" (including

scirrhus) has increased in rate from 26.1 in 1908 to 69.5 in 1929, the rates for epithelioma, rodent ulcer, and sarcoma have remained constant. The whole increase in cancer in all sites in all countries is in "glandular" cancer—other forms of malignant disease have shown no change in incidence.—*Med. Off.*, 48:3 (July 2), 1932.

## PUBLIC HEALTH ENGINEERING

### REFUSE DISPOSAL IN THE CITY OF VIENNA

E. A. SWEET

*Medical Director, U. S. Public Health Service, Ellis Island, N. Y.*

THE collection and disposal of refuse naturally bear a certain relation to health conditions. While in most American cities the care of garbage and other house refuse is now ordinarily under the control of a branch of the city government separate from the health department, or is let out to private contractors, nevertheless the health officer is frequently called upon to express an opinion regarding particular measures advocated, and in some instances at least must actually supervise work along this line. For these reasons, therefore, he should be acquainted with the various aspects of the refuse disposal problem.

In general it may be said that European cities have progressed further in the handling of refuse than American communities. Perhaps one should also add that refuse is less a problem in Europe than in America, there being a number of reasons for this.

First, the fuel consumption per person is higher with us than in Europe, with a corresponding increase in the output of ashes. Second, we are more wasteful than our cousins across the

water, the European housewife being horrified when she inspects an American garbage can. Third, such rubbish as newspapers, discarded magazines, tin cans, and the like, in America exceeds by far the amount of similar material in an average European city.

In 1928 the city of Vienna completed the introduction of a system of garbage collection which has many advantages over the haphazard methods which often prevail. Prior to this time the refuse was collected in open wagons, the driver announcing his arrival by the sounding of a gong, whereupon the respective maids of the various tenants rushed to the street carrying containers of one sort or another for emptying. At its best the old system was more or less unsightly, resulted in disagreeable odors, and disseminated the maximum amount of dust. Before introducing the present system the situation was carefully investigated in order to avoid mistakes and to determine what appeared most desirable from an economic and sanitary standpoint.

The new method provides for the handling of refuse by the city without

cost to the individual householder. Instead of each household purchasing its own container, of such design as appeared most suitable, the city decided to furnish uniform cans to the various apartments in proportion to the number of residents therein, these to be used in common by the respective families.

imagine. The placing of the units in cellars or basements is naturally avoided on account of the difficulty in handling.

In the new apartments recently erected by the city, housing 2,000 or more, special rooms have been set aside for garbage containers and they are handled expeditiously by means of

TYPE OF CONTAINER IN USE

The choice of location of the garbage cans is determined upon following a conference of the representative of the city with the house administrator or janitor. It is of course desirable that the containers be easily accessible not only to the householder but also to city employees, and that the carrying distance to the sidewalk be relatively short.

Eighty-nine per cent of all receptacles are located either in the garden or the hof, the latter being the central space around which European apartments are usually built. Five per cent are at the entrances, another 5 per cent are either in cellars or other space below the street level, and the remaining 1 per cent are distributed in miscellaneous places. Inasmuch as the cans are seldom if ever unsightly from overflowing or from the scattering of waste, their location in the hof or near the entrance of buildings is less objectionable than one would

electric trucks. The walls of such rooms are tiled, the illumination is adequate, and satisfactory ventilation is secured by means of electric exhausts, so that disagreeable odors are not in evidence.

All cans throughout the city are raised at least 6 inches from the floor or ground level by means of a metal frame of substantial construction built into the wall of the house, the upper handles of the container fitting into corresponding niches in the arms of the frame. The purpose of this elevation is threefold. It enables the householder to maintain a high degree of cleanliness, as the area around and underneath the containers is thus easily swept, and further prevents upsetting with consequent dumping of contents. It also effects a considerable saving by preventing deterioration through the action of snow and rain.

The cans are constructed of somewhat

heavier metal than is customary in America; hence long life with absence of leakage is assured. Reference to the accompanying illustration will show their general character. The two handles on each side, the lower set being placed anterior to the upper, facilitate handling, especially when the receptacles are lifted to the wagons.

The cover is the distinguishing feature of the container. Instead of being removable it is attached to the main body of the can by an arm or radius in such a manner as to slide backwards or forwards by traction on the fifth handle. The cover is so tightly fitted that access of rodents is prevented. Flies are also discouraged from entrance, as the only way they can reach the contents is by crawling through the narrow space between the cover and the side. However, the body of the container is ribbed at its upper edge, so that this space is considerably narrower than it appears. A small projecting arm on each side enables the can to be suspended to the corresponding unit of the collecting wagon.

No separation of the refuse into its various constituents, ashes, table waste, and papers, is attempted, all going into the same receptacle. Chemicals, fluids, and excessive amounts of animal waste from butcher shops and the like are prohibited.

The collecting part of the system consists of two conveyors or wagons detachable from the hauling unit. While such a train is less easily manipulated, especially in narrow streets, than a single truck, the authorities claim that the motor unit is more frequently out of service through mechanical defects than the trailers, therefore a saving is effected.

Each trailer is equipped with a series of twelve closed receptacles or units, corresponding closely in size with the cans, leading into the main undivided body of the wagon. The can is lifted

from the curb to the most convenient receptacle by two men, is suspended on projecting hooks, and is then tilted. The tilting simultaneously retracts the cover to the can and pushes back the cover of the receptacle, so that the contents are emptied without dust, unsightliness, or other objectionable feature, the entire procedure occupying only a few seconds.

The collecting wagons have a personnel of 5, not including the driver. Two men precede the trucks and bring the containers to the curb, 2 men attend to the emptying, and the 5th, equipped with a hooked strap hung over the shoulders, returns the cans, two at a time, to the racks. In this manner neither the filled nor empty containers remain for any considerable period on the street.

On financial grounds, collection is only possible once in 10 days. It is realized that this interval is too long and an attempt will be made to shorten the period to 1 week. Hotels and institutions are provided with a shorter service.

The ultimate disposal of the refuse is by dumping at a point within easy reach of the center of the city. Naturally, this method is objectionable, but money has not been available for the erection of incinerators. When the present dump is filled, estimated to require 4 years, the cost of the longer haul will probably exceed the cost of incinerators, therefore incineration will be provided for on economic grounds.

Upon reaching the dump the refuse wagons run upon a trestle and their contents are discharged into smaller cars below, these cars being hauled by a caterpillar tractor to the outer limits of the dump.

Glass, metal and cloth are sorted out, the contractor paying approximately \$7,000 a year for the privilege. On account of smoke, burning is not attempted. Similarly, no effort is made to limit the breeding of flies by cover-

ing with earth, but the usual petroleum compounds are used, especially in years when flies are prevalent. Complaints of insanitary conditions, less perhaps of odors than of flies and rats, are of course received.

Altogether, the care of refuse in the homes, and the collecting system, are about as satisfactory as one could desire. The standing of boxes, pails and containers filled with rubbish on the sidewalks awaiting collection has been entirely eliminated. There is no dust during the emptying process or when the trucks are driven through the streets, even on windy days. Sometimes a workman will retract the cover to the can to determine if it has been completely emptied, and a small amount of dust will result, but such action is not necessary. The rubbish cannot be seen, which is of course a decided advantage.

The cost has not been excessive. Roughly, Vienna pays \$825,000 an-

nually for this collecting system, which amounts to \$.45 per person. Based upon the number of cans emptied, each of which holds 90 liters, the cost has been \$.13 per unit. In making estimates for the United States the difference in the quantity of refuse must be considered, as well as the price of labor, the average Viennese worker receiving \$11 weekly.

There are approximately 180,000 cans in service, costing \$4.50 each. An increase of from 3 to 5 per cent in the amount of garbage is noted yearly, and the difference between the summer and winter amounts is around 20 per cent. Only 30 of all the receptacles in use have been lost during the past 3 years. A shop where the cans are washed and renovated, is maintained.

The writer knows of no reason why a garbage collection system such as the foregoing, the advantages of which are at once apparent, is not feasible in the average American city.

COLLECTING WAGONS

## INDUSTRIAL HYGIENE

**Compensation for Silicosis in New South Wales—Summary:** The workmen's compensation law of New South Wales is exceptional among the workmen's compensation laws of British dominions in that it contains no schedule of "industrial diseases," but covers injuries by disease in indefinite terms. Under that law, compensable injury includes

. . . a disease which is contracted by the worker in the course of his employment . . . and to which the employment was a contributing factor, but does not include a disease caused by silica dust.

Under this provision, the practice has developed of referring claims for injury by disease to, and for determination by, medical boards or a medical referee. In the fiscal year 1930-1931 there were 165 awards for diseases in comparison with 27,180 awards for accidents. The preceding matter refers to the general law. In addition, under special provisions of law, there have been organized schemes insuring medical benefits and compensation for certain pulmonary diseases to workmen employed in a few specified occupations in several localities.

The *Fifth Annual Report* of the Workmen's Compensation Commission of New South Wales, for the year ending June 30, 1931, gives a significant account of the operation of "Workmen's Compensation (Silicosis) Scheme, No. 1," from its initiation September 16, 1927, to June 30, 1931. This scheme of providing medical benefits and compensation for silicosis, which is publicly administered, covers stone masons, quarrymen, rock choppers, and sewer miners in the County of Cumberland only. Workmen examined during that period numbered 2,231, of whom 113

were suspended upon initial examination; 117 were found to be suffering from silicosis to a dangerous degree; 88 were found to be suffering from it but not to a dangerous degree; 1,899 were found to be free from the disease; and 14 examinations were pending.

The original plan of finance called for contributions from employers of 3 per cent of wages and equal contributions by the State; but the State has been backward about paying up. Assuming that the employers and the State both contribute in full, it is estimated in the report that, for the year 1931-1932, a current cost deficit of £7,303 will be incurred, and that, at the end of the year, there would remain outstanding *contingent liabilities of approximately £44,372*. An increase in the rate of employers' contributions to 5 per cent is suggested, but it is intimated that even such increase in contributions would not be adequate without increased help from the State.

The data in this report, just cited, are rather incomplete and somewhat speculative, but they indicate that the cost of compensating for silicosis (which is additional to the cost of compensating for injuries covered by the general compensation law) is running up to nearly 10 per cent of wages. In consequence of this discouraging experience, a movement to extend this scheme of compensating for silicosis to cover all New South Wales has subsided.

The lesson of this seems to be that permanent disablement by silicosis is not a matter for compensation but for the strictest prevention—by frequent medical examinations to eliminate from employment in the occupations subject to such disease all persons predisposed

to pulmonary troubles or manifesting the first symptoms of such troubles.

The only practicable alternative seems to be to condition the right to compensation for disablement by silicosis upon at least 5 years' exposure to the risks of the occupation and upon truthful answers to interrogatories as to previous health and employment, and, then, for the compensation insurance carrier or carriers to insist upon periodical medical examination of employees in occupations exposed to the disease, with a view to the early elimination from the occupation of all workers manifesting the first symptoms of any pulmonary weakness.—*Bull. Assoc. of Casualty & Surety Executives*, No. 30: 6-7 (June), 1932.

E. R. H.

**Dust as an Industrial Hazard—**This is a rapid survey of the various phases of dust as an industrial problem.

The kinds of dust are classified as poisonous and non-poisonous, the latter subdivided into organic and inorganic, or mineral. The mineral subdivision includes (1) non-silica dust such as coal and lime; (2) combined silicates such as clay, talc and feldspar, and (3) silica which may exist as pure silicon dioxide or sand, granite, quartz, and the various kinds of sandstone. There is some difference of opinion as to whether combined silicates and silica can be considered non-poisonous. Evidence would in recent years attribute its harmful influence to chemical properties.

There is a brief discussion on what happens to inspired dust (with an accompanying sketch of lung cell in relation to blood and lymph vessels). The findings of Mavrogordato, Collis, and Heffernan are cited. Asbestos is also referred to.

The chief discussion concerns silicosis in respect to four important points: (1) particle size; (2) number of particles per cu. ft. of air; (3) mineral composition of the dust; and (4) the

length of exposure. As a general statement, if the silica content of any given dust is 35 per cent, the standard of safety can be placed at approximately 15 millions particles per cu. ft. of air in the breathing zone of the workmen. If the dust has a silica content of 70 per cent, the margin of safety will be approximately  $7\frac{1}{2}$  million particles. At 90 to 100 per cent of free silica, as in the case of sand blasting, the standard is placed at approximately 6 million particles.

Methods of protection, legislation in certain Canadian provinces and the fact that 6 states in the United States cover silicosis (in compensation matters) are pointed out. These states are California, Connecticut, Maryland, Massachusetts, North Dakota, and Wisconsin. Hawaii is also included.—C. O. Sappington, *Industrial Health Digest*, Natl. Safety Council, 20 North Wacker Drive, Chicago (Mar. and Apr.), 1932.

E. R. H.

**Department of Industrial Hygiene—**Dr. Mavrogordato states that investigations were carried out in association with a Joint Committee of the Mines Department and the Chamber of Mines that has been attempting to work out improvements in the method of estimating air-borne dust as at present in use on the gold mines of the Witwatersrand.

The gravimetric method as at present used does not deal with a sufficient volume of air to meet existing conditions, while the konimetric method is unsatisfactory because total air-borne dust and air-borne phthisis-producing or "intractable" dusts vary independently. Methods have been devised for so treating the konimeter-spot that dust, other than "intractable" dust, is eliminated. Several preliminary reports have been submitted.

At the International Silicosis Conference held during the year at Johannesburg, it was agreed that none of the

existing methods of estimating air-borne dust met present-day needs, and South African workers were invited to devise a method of dust-estimation that could be standardized for general use. This investigation will shortly be in hand.—*Ann. Rep. South African Institute for Medical Research, for the year ended December 31, 1930, Johannesburg (1931)*, pp. 24–25. E. R. H.

**Investigation of Air Outlets in Class Room Ventilation**—In this study the air passing out of school room ventilation outlets was determined. It was found to be 55 per cent of the computed value for buildings of comparatively poor design from the viewpoint of air leakage and 75 per cent in buildings of good construction. The study of window ventilation showed an inflow on both windward and leeward sides ranging from 200 to 500' per minute.—G. L. Larson, D. W. Nelson, and R. W. Kubasta—*Heating, Piping & Air Conditioning*, 4, 7: 509–515 (July), 1932. L. G.

**The Health of the Industrial Worker**—This paper is from the viewpoint of disease compensation.

Modern industry has conferred benefits on the human race, whether estimated by improvement in health, or by increase in population. Nevertheless, occupational hazards exist, which determine the occurrence of various kinds of incapacity; for these occurrences compensation is awarded. They weigh heavily upon some industries, foremost among which stands coal mining. Here miners, who only comprise 12.5 per cent of insured persons, account for 42 per cent of claims for accidents, and for 86 per cent of claims for diseases; while 23 per cent of these miners claimed compensation in some form in 1929.

Among diseases not peculiar to the province of coal-mining, inflammations of the skin and skin-cancers are calling

for increasing notice, and pointing to the way in which cancers originate.

The dust-disease, silicosis, which is dealt with separately under the Compensation Act, is likely to be found the most serious of all occupational diseases when reliable records have been amassed.—Edgar L. Collis, University of Wales, *J. State Med.*, 40, 2:96–105 (Feb.), 1932. E. R. H.

**Hygienic Instructions for Working Men**—These instructions cover many special situations in industry and refer to food, water drinking, clothing, fresh air, recreation, bathing and personal hygiene, sleep, care of teeth, constipation, colds, and headache.—May R. Mayers, *Indus. Bull., New York Dept. of Labor*, 11, 7:225–226 (Apr.), 1932. E. R. H.

**The Program of the Department of Labor and Industry for the Prevention of Industrial Disease**—Among features discussed are the following measures adopted by the Industrial Board as of April 15, 1932:

All dust, fumes, vapors, gases, fibres, fogs, mists, or any other atmospheric impurities that, in connection with any process of manufacture or use, are created in, emitted into, or disseminated through areas where persons are employed, in such quantities as in the judgment of the department, would (or might) tend to injure the health of employees, shall be removed by means of suction devices at their point of origin or by other methods acceptable to the department.

When required by the department the employer shall have determinations made of the kind and amount of the atmospheric impurities from a sample taken under conditions and at a point or points indicated by the department. This shall be performed by an analyst qualified for the purpose.

The quantity of any impurities as shown by the determinations shall not be of an amount considered by the department to be injurious to the health of the employees.—

Charlotte E. Carr, Labor and Industry, Pennsylvania Dept. of Labor & Industry, 19, 5:1–3 (May), 1932. E. R. H.

**Silicosis**—Mr. Tinker asked the Home Secretary the number of work-people in the coal-mining industry suffering from silicosis during the latest 12 months for which figures were available and the number who received compensation for this disease, giving separate figures for Lancashire. Sir Herbert Samuel replied: "Silicosis is not notifiable and the only figures I can give are those of cases under the Workmen's Compensation Act. The Returns under that Act show that in 1930—which is the last year for which figures are at present available—there were 20 cases in which coal-miners recovered compensation for disablement from silicosis. Information as to the distribution of these cases is not complete, but so far as known, only one of them occurred in Lancashire. I may add that I am informed that the Medical Board, which was set up in June last, has not so far issued any certificate in respect of any coal-miner in Lancashire."—*Lancet*, 5671:1019 (May 7), 1932. E. R. H.

**Morbidity and Mortality of South African Miners**—The Report of the Sanitation Department of the South African Central Mining-Rand Mines Group for 1931 contains statistical information comparing health conditions during the period with those of earlier years.

The average number of natives employed was 82,416, as against 79,742 in 1930 and 83,340 in 1929.

The percentage morbidity and mortality rates given for the various diseases include the following: pneumonia, 32.61 per cent of total mortality; typhoid fever, 11.06 per cent of total mortality. Accidents accounted for 56.41 per cent of the total morbidity and 23.25 per cent of the total mortality.

The incidence of pneumonia decreased after the cessation of inoculation against the disease. This confirms an exhaustive account of the negative results of inoculation in pneumonia prevention published in the *Journal of the South African Medical Association* in the course of the year.

The tuberculosis rate fell from 5.12 per 1,000 in 1930 to 4.67 per 1,000 in 1931. There were 385 cases with 75 deaths, or a death rate of 0.91 per 1,000.

A comparison of the rates for miners' phthisis in the last 3 years shows a steady decline in the incidence of this disease. The returns for 1931 are as follows: 0.91 cases per 1,000 and 0.05 deaths per 1,000.—

*Indust. & Labour Inf.*, World Peace Foundation, 30 Mt. Vernon Street, Boston, 42, 3:79-80 (Apr. 18), 1932.

E. R. H.

**The Technic of Experimental Pneumoconiosis**—Author's conclusions:

1. A technic is described for the introduction of dust into the lungs of experimental animals by intratracheal injection.

2. The reaction of the lung to dust introduced by this methods is essentially the same as to dust introduced by inhalation.

3. The results obtained indicate that the direct intratracheal injection of dust into the lungs may advantageously replace the dusting chamber for many purposes for which it has hitherto been considered necessary.—

E. H. Kettle and R. Hilton, *Lancet*, 5675:1190-1192 (with plates) (June 4), 1932. E. R. H.

**Tuberculosis in South African Natives With Special Reference to the Disease Among the Mine Labourers on the Witwatersrand**—This extensive volume is the report of the Tuberculosis Research Committee originally established by the Transvaal Chamber of Mines and later expanded into a Joint Committee by incorporation of representatives of the Union Government.

The chapter headings are: General considerations, anthropological and historical notes on the Bantu Tribes of South Africa; reports on tuberculosis of South African Natives prior to the present inquiry; the principal industries and occupations in which natives are engaged in South Africa; the gold mining industry and health; health services in

the gold mining industry; the tuberculosis of native mine workers on the Rand—with sections on tuberculin tests, tuberculosis in the Native Labour Association's Hospital and in the mine hospitals, incidence and mortality from tuberculosis, pathology and classification of clinical types; tuberculosis survey of the native territories; inferences drawn from the foregoing chapters; and discussion on prophylactic measures now in force or capable of being applied in South Africa.

A summary of the recommendations of the committee is given on pages 297–300. The balance of the volume (pp. 301–429) is devoted to appendixes, carrying tables, charts, and case reports by various authors. The volume is profusely illustrated, including 24 plates, part of which are in colors which depict sections of the lungs and other organs undergoing pathological changes due to silicosis and tuberculosis. The volume is too extensive for further abstracting.—South African Institute for Medical Research, Johannesburg, *Publications*, Vol. 5 (Mar.), 1932. 429 pp. E. R. H.

**Extensions of the Schedule of Industrial Diseases**—This is a report of the Secretary of State by a Departmental Committee on Compensation for Industrial Diseases under Section 43 of the Workmen's Compensation Act, 1925. The matters considered were, poisoning by turpentine, mule spinner's cancer, and dope poisoning.

The committee concluded that no case had been made out for adding poisoning by turpentine to the schedule.

In regard to mule spinner's cancer a definition was agreed upon as follows: "a localized new growth of the skin, papillomatous or keratotic, due to mineral oil," this to be inserted in the first column of the schedule. In regard to the second column, the committee recommended the insertion of the words

"cotton spinning by means of self-acting mules." The person undergoing treatment for such localized new growth shall not be entitled for compensation for more than 14 days, unless the judge, committee, or arbitrator, is satisfied, on the advice of the medical referee, that the worker is still incapacitated for work.

In regard to dope poisoning, the committee concluded that it would not be right on the evidence at present available, to add to the present schedule poisoning by any particular substance used as, or in conjunction with, a solvent for nitro-cellulose or poisoning by such solvents generally. It stated that the occurrence of chronic poisoning by any particular substance so used, other than the substances now separately dealt with in the schedule, had not been established; and to include poisoning by all such substances in general terms would be unfair to manufacturers and others, and would go far beyond what would be necessary for the protection of the workmen.—Home Office, Great Britain, London, 1932. 16 pp. E. R. H.

**Mule Spinners' Cancer Made Compensable in Great Britain**—An order dated April 30, 1932, of the British Secretary of State, provides for the inclusion of new skin growths due to mineral oil in the list of compensable diseases. The order applies to workmen engaged as "minders" of self-acting spinning mules.—*Month. Labor Rev.*, 35, 1: 93 (July), 1932. L. G.

**Hospital and Institution Fires**—This is a record of 202 hospital and institution fires with a detailed discussion of the major ones which have occurred since 1918 with illustrations and discussions. There is particular space given to fires from X-ray films.—National Fire Protection Association, 60 Batterymarch St., Boston, Mass., Nov., 1931, 66 pp. E. R. H.

## FOOD AND NUTRITION

**Milk Irradiated by the Carbon Arc Lamp**—Fluid milk was irradiated with a flaming carbon arc lamp using a C carbon. Three and one-half million ergs were applied per c.c. of milk for 16 seconds, between 2,000 and 3,000 Angström units. Most of the vitamin D potency is reached in the first few minutes of irradiation.

The investigation was conducted with children similar to the case of the yeast milk experiments of 1931 (*J. A. M. A.* 97:370, Aug. 8, 1931). Over 100 babies between 1½ and 6 months of age were selected from clinics of the Department of Health of New York.

Infants were weighed regularly and frequent roentgenograms of the wrists taken. Through the period from the beginning of January to the end of March, the babies took 24–30 ounces of milk daily, supplemented in the older groups by cereals and vegetables. Many of the infants were negroes, and Puerto Ricans.

Of the 36 babies which had no evidence of rickets in January, all but one failed to show roentgenologic signs of rickets at the end of the trial; the exception was a premature baby which is regarded as a type in which rickets cannot be prevented except possibly by the use of excessive amounts of viosterol. In the larger group with rickets, those of the roentographic type were definitely healed within a month or 6 weeks.

In the so-called clinical rickets where satisfactory results were obtained, the criterions of healing were recession of the beading of the ribs, diminution of craniotabes, or intensification of calcification of the epiphyses. Craniotabes often fail to show recession even with fortified cod liver oil, leading to the belief that in this disorder there is an

essential factor aside from lack of vitamin D.

The conclusion is drawn that activated milk is at least as efficacious as the "yeast milk" described in the previous paper. Reference is made to the observations of the varying degree of antirachitic potency between cod liver oil and activated ergosterol. This clinical evidence warrants the conclusion that the activated milk is in the class with "yeast milk" and cod liver oil rather than of viosterol. A quart or less of this milk protects infants from rickets although it contains only 50 units of vitamin D by the standard technic.

The authors discuss the antirachitic agents in 6 classes—(1) irradiated milk, fluid and dry; (2) "yeast milk"; (3) cod liver oil; (4) viosterol; (5) irradiated yeast, and (6) direct ultraviolet irradiation. The antirachitic milk has certain advantages as recent tests have shown that 10,000 to 15,000 times the therapeutic dose could be given young rats without resulting in hypercalcemia. Irradiated milk is inexpensive although probably not available except in urban communities. There is no belief that flash irradiation results in the formation of any harmful products. Milk from cows receiving irradiated yeast is also regarded as valuable. Cod liver oil is valuable and may possess a factor not yet recognized but objection to its use is general on account of the taste and odor.

The most powerful of antirachitics is viosterol which it is believed should be reserved for cases resistant to other methods and applicable in communities where irradiated milk or "yeast milk" is not available.

The question as to whether there is

danger in multiplication of foods fortified by antirachitic vitamin is discussed, as well as the desirability of adults partaking indiscriminately of such foods. The question is also raised as to whether Federal license and supervision should be required before antirachitic foods are permitted on the market.—A. F. Hess and J. M. Lewis, *J. A. M. A.*, 99:647 (Aug. 20), 1932.

**The Reaction of the Chicken to Irradiated Ergosterol and Irradiated Yeast as Contrasted with the Natural Vitamin D of Fish Liver Oils—**The literature records instances where irradiated ergosterol does not give the same quantitative results for vitamin D as cod liver oil when fed experimental animals.

In these experiments, 2- to 3-day old chicks were used—white Leghorns and Plymouth Rocks—with 15 to 20 birds in each group. The diet was skim milk as a drink with a dry mash of yellow corn containing calcium carbonate and sodium chloride. The ergosterol was incorporated in corn oil. Dry, ground yeast was also fed, having an anti-rachitic potency of 0.5 Steenbock rat units per mg. The cod liver oil contained 13.3 rat units per gm.—the amount of vitamin D which will produce a narrow line of calcium deposit in the radii and ulnae of rachitic rats in a period of 10 days.

Two of the series with cod liver oil and its equivalent as ergosterol showed that from 40 to 120 times as many units of vitamin D in the ergosterol were required to effect calcification as compared to cod liver oil. The yeast was a poor calcifying source requiring 7.5 to 60 per cent cod liver oil equivalence as yeast to produce the same results. This represents an actual consumption of 0.2 and 1.6 per cent respectively of the weight of the dry mash.

The natural source of vitamin D was also investigated in burbot liver oil,

already shown by other workers to contain vitamin D. Thirty-six baby chicks were divided into 3 groups, one on a rachitic ration, another on the same ration plus 1 per cent cod liver oil, and the third with a basal ration plus 1 per cent burbot liver oil. In this series, burbot liver oil was equally efficient per rat units of vitamin D as cod liver oil. In order to determine whether the vitamin D resulting from irradiation was a different substance, irradiated ergosterol was dissolved in cod liver oil to determine whether greater calcification would result than with the cod liver oil alone.

One lot of rachitic birds were given the basal ration plus 2 per cent of cod liver oil having in solution 532,000 rat units of vitamin D as irradiated ergosterol. Another lot was given the same dose of ergosterol in corn oil instead of cod liver oil and a third lot were controls. The irradiated ergosterol represented the equivalent of approximately 40,000 per cent of cod liver oil.

The final weights of the birds on irradiated ergosterol were less than both other controls. There was no change in the ash of the tibiae. The blood serum calcium increased with both solvents and the inorganic phosphorus in the serum reduced.

Another series was run in which the dosage of the irradiated ergosterol was reduced to 100,000 and 250,000 rat units of vitamin D per 100 gm. of the ration. The experiments were conducted for 32 days and similar results were obtained in this series. Loss in body weight compared with initial weights of 250,000 units. No characteristic change in the ash percentage of the tibiae but serum calcium was increased and the serum phosphorus decreased.

Further experiments were undertaken on the curative effect of ergosterol with small amounts of cod liver oil. The ergosterol was equivalent in vitamin D

units to 1 per cent of cod liver oil and was fed with 2 cod liver oil levels—namely, 0.05 and 0.10 per cent, these amounts of cod liver oil having little or practically no effect on calcification.

The irradiated ergosterol in this experiment had absolutely no effect on calcification, while 1 per cent of cod liver oil was very effective. Typical symptoms of toxicity were found with the irradiated ergosterol in excessive doses, manifested by anorexia, loss in body weight, and in the loss of weight in the dry organs. The administration of carotene had no effect on the antirachitic activity of irradiated ergosterol.—H. Steenbock and S. W. F. Kletzien, *J. Biol. Chem.*, 97:249 (July), 1932.

**The Effect of Oral Administration of Amino Acids and Intraperitoneal Injection of Various Elements and Hydrochloric Acid on Regeneration of Hemoglobin**—The literature contains conflicting statements as to the necessity for supplementing iron with copper in hemoglobin regeneration. Investigators also state that other elements than copper as well as amino acids may have this effect. This experiment was designed to study the effect of amino acids, iron alone, iron supplemented with other elements and, if possible, the amount of copper necessary to supplement iron.

Rats were made anemic with milk from Holstein cows, milked in glass containers. Amino acids were purified and the iron freed completely from copper as shown by spectroscopy.

After 1 month on the milk diet, 100 mg. of the different amino acids—tyrosine, tryptophane, glutamic acid, aspartic acid, and arginine—were added plus 0.5 mg. of iron as ferric chloride. No regeneration of hemoglobin resulted with the amino acids. No appreciable difference in effect was noted between 1, 5 and 10 mg. of iron daily.

Animals on a milk diet with added

ferric chloride were given intraperitoneal injections of the following elements: nickel, zinc, germanium, manganese, vanadium, arsenic, titanium, selenium, mercury, rubidium, chromium, and 0.005 mg. copper. Arsenic caused an immediate regeneration but after 3 weeks this was lost and no such initial effect appeared in the other elements. None of these, except copper, prevented anemia. The intraperitoneal injection of ferric chloride, if dissolved in glycerol to avoid irritation, caused an increase in hemoglobin.

The authors are in doubt as to whether under these conditions the iron is utilized to the exclusion of copper or whether the difference between oral and intraperitoneal feeding may be due to absorption of iron. When pure ferric hydroxide was injected intraperitoneally to anemic rats, to which were given 0.05 mg. of copper as copper sulphate daily, the hemoglobin response was satisfactory, although there was no regeneration in the anemic rats fed milk without copper.—H. L. Keil and V. E. Nelson, *J. Biol. Chem.*, 97:115 (July), 1932.

**Carotene and Xanthophyll as Sources of Vitamin A for the Growing Chick**—Xanthophyll and carotene in this experiment were isolated from fresh spinach leaves. The recrystallized xanthophyll had a melting point of  $174^{\circ}$  and the carotene  $172.5^{\circ}$ . These were dissolved in cottonseed oil so that 0.5 c.c. of oil contained the daily dose of pigment which was fed to the chicks with a pipette.

Day old white Leghorn chicks in 9 groups were kept in warmers in a semi-darkened room. The basal ration was white corn, wheat middlings, casein, yeast and salt. Six of the group were for a prophylactic experiment and 3 for curative. In the prophylactic group, comparison was made between the basal ration and this ration with 0.5 c.c. cod liver oil added to the ration with 0.03

mg. carotene and with 0.25 mg. xanthophyll.

In the curative test the carotene was 0.05 mg. and the xanthophyll was slightly decreased. Vitamin D was supplied, except in the cod liver oil group, by direct irradiation. Good growth resulted in all groups to the 4th week when the chicks on the basal ration developed vitamin A deficiency followed shortly by death. Good growth resulted on the cod liver oil supplement with 0.03 mg. carotene. Xanthophyll supplement and the one in which cod liver oil was supplanted with cottonseed oil showed no advantage over the basal ration. In the curative technic, xanthophyll resulted in no gains, but with 0.05 mg. carotene the effect on growth and appearance was remarkable.

The feeding of xanthophyll in these experiments did not increase the yellow pigment in the legs and beaks of the chicks. It was also found that after the chicks reached 7 to 8 weeks 0.03 carotene daily is not sufficient as the sole source of vitamin A.—O. L. Kline, M. O. Schultze and E. B. Hart, *J. Biol. Chem.*, 97:83 (July), 1932.

**Production of Vitamin A by a Species of *Corynebacterium***—Although the literature records the production of vitamin B complex by means of bacteria, there is no conclusive evidence of the synthesis of vitamin A by a number of different strains of various organisms. In this work a species of *Corynebacterium* was grown on a vitamin free medium of dextrose, agar, peptone, and distilled water. Cultures were incubated at room temperature in total darkness.

The rats used were healthy but approached both vitamin A and D deficiency. After definite A deficient symptoms appeared, the rats were divided into lots receiving separately the ration plus 1 drop of cod liver oil per day, one with no supplement, and the

third with a supplement of 1 gm. of dried bacteria. The results of this experiment showed a definite growth in the case of rats on the bacteria supplement. To insure absence of vitamins in the ration control supplements were run on the animals with xerophthalmia.

One lot received no further treatment, the second, cod liver oil, the third, the diet in which casein was replaced by peptone and one-half the dextrin by dextrose, and the fourth, the same as the third but with the cod liver oil. The result showed no appreciable amount of vitamin A in the culture medium. Xerophthalmia was cured and slight weight gains recorded.—C. E. Skinner and M. F. Gunderson, *J. Biol. Chem.*, 97:53 (July), 1932.

**Idiosyncrasy to Viosterol**—Gordon and Lieberman administered irradiated ergosterol in the form of viosterol (100 D and 250 D) in doses of 1 to 9 drops a day to 200 infants, who were observed over a period of from 6 months to 1 year. Untoward symptoms were noted in 15 in the following order of frequency: diarrhea, vomiting, loss of appetite, colic and stationary or loss of weight.

No case was included in this group unless a definite sequence was obtained, consisting of administration of the drug, appearance of ill effects, subsidence of the latter on suspension of the drug and finally reappearance on the resumption of viosterol.

From their study the authors conclude that a definite pharmacologic idiosyncrasy to minute amounts of irradiated ergosterol (viosterol 250 D) exists in some infants. According to the incidence found in their series, this is of more frequent occurrence than the literature indicates. The drug should be suspended on the appearance of any ill effects and permanently discontinued in the event of reappearance of symptoms on its resumption. The idiosyn-

crazy to viosterol may not be permanent. The possibility of an idiosyncrasy should in no way detract from the general use of viosterol in either the prophylactic

or the therapeutic treatment of rickets. —*Am. J. M. Sc.*, 183 (June), 1932. *Abstr., J. A. M. A.*, 99:684 (Aug. 20), 1932.

## CHILD HYGIENE

### ORAL HYGIENE

ORAL hygiene is assuming more and more importance in the child hygiene program. It is increasingly evident that, in order to make any perceptible impression on dental caries in our school population, mouth hygiene must begin prior to school entrance. After the children have entered school, extraction and filling of cavities make up the bulk of the dental work.

The relation of nutrition to oral hygiene has received considerable attention in recent years. There appears to be very little doubt that proper nutrition of the pregnant mother and of the child in its early years conditions, to a large extent, the outcome of the teeth. Undoubtedly certain hereditary factors play a part, but these may be modified considerably by nutrition, freedom from infectious diseases, and other environmental factors.

Reorganization of dental facilities is now under way in a number of places to meet the needs of both the preschool and the school child. The economic as well as the technical problems connected with oral hygiene must receive serious attention. The Odontological Society of Western Pennsylvania is attempting to solve the problem in Pittsburgh with a minimum expenditure on the part of the community.

This society has established fourteen emergency dental clinics in the western part of Pennsylvania, concentrating services on the 6-year molar and deciduous teeth and using only temporary filling materials. In the clinic in Pittsburgh it has taken care of 1,266 patients in 4 months' time, at a cost of less

than 9 cents per patient. This has included 1,328 extractions and 1,272 fillings.

How has this been done? Efficient management under the direction of an exceptionally capable secretary has been the keynote of this success. Dr. W. Earle Craig, the secretary, finds time in a busy practice of dentistry to manage the affairs of his society with the same interest and effectiveness he would devote to a private enterprise. His earnest efforts, combined with an ability to obtain coöperation from fellow members, have made his administration a splendid example of good dental society management. He has been ably assisted in this clinic work by a committee consisting of Dr. J. K. Wampler and Dr. Leslie Waddill.

Here are the steps followed in the organization of this clinic. *Oral Hygiene*<sup>1</sup> presents them with the thought that they may be helpful to other societies:

1. A committee of three was appointed to promote and manage the clinic.
2. One hundred and fifty members donate their services. Each operator serves a half day at a time, two being on duty in the morning and two in the afternoon.
3. The local charity organization donates the services of a nurse and attendant.
4. The clinic was furnished in the following manner:
  - a. The leading professional building donated three offices.
  - b. Local dental supply houses loaned the complete equipment.
  - c. The local telephone company installed telephone service at the charity discount rate and the Child Health Council takes care of the bill.
  - d. A local printing concern donated admission and record cards.
  - e. The building donated the plumbing fixtures and service.
  - f. A local towel supply house launders the towels which were donated by members.
  - g. Anesthetic gases were donated and

two of the local exodontists care for difficult cases in their own offices.

h. Dentifrice concerns donated tooth paste and the Oral Hygiene Committee of the society provided toothbrushes.

i. Stationery, signs, etc., donated.

j. Dental materials are provided at cost price.

k. Local newspapers were generous in giving publicity and school authorities have coöperated in investigating needy cases and bringing children to the clinic.

A great deal of good has been done by this clinic in the few months it has operated and this without working a hardship on any one person or concern. The society regards the clinic as a temporary emergency effort during present-day conditions.

The needy must be cared for and if organized dentistry does not do it we can look for outside and perhaps unwelcome intervention.

An unusual and radical method of handling the same problem is being carried out in New Zealand. In the current issue of the *Journal of the American Dental Association*<sup>2</sup> it is pointed out that—

The problem of the dental treatment of school children and their instruction in the principles of dental hygiene is being attacked in various ways in different countries. Here, in the Dominion of New Zealand, the government is developing a system which may, at first sight, shock many of the members of our conservative profession by reason of its unorthodox features, but which, on closer investigation, must, I am sure, appeal to all thinking men and women as providing an essentially sound and logical means of solving the problem.

The main feature of the New Zealand service is that the school children are cared for not by dental surgeons but by a corps of specially trained dental nurses. The government established the school dental service soon after the conclusion of the World War. Indeed, it is probable that the decision of the government to do this was influenced by the fact that, during the war, so many men were rejected for service in the army, either temporarily or permanently, on account of dental defects. The constant representations made by the dental profession of the dominion over a period of some 20 years in favor of establishing a school dental service no doubt also helped to influence the government in its decision to develop such a service.

One of the dominion's leading practitioners who had been in charge of the army dental service during the war was selected to organize and direct the new service. The problem that confronted him was no easy one. Consideration of all circumstances led to the decision to create an entirely new type of operator who, as officers of the department of health, would deal only with children in the schools. As was only to be expected many of the members of the profession were startled by so revolutionary a proposal, and at first many objections were raised.

After many frank and full discussions and the consideration of alternative schemes, this proposal was officially approved by the New Zealand Dental Association as the one best calculated to solve the problem. Indeed, the association has taken a very live interest in the development of the service and has on more than one occasion endorsed it. As with all such services, the ultimate aim is to help to raise the standard of general health of the community by eliminating oral sepsis among the children, by ensuring that they have sound teeth with which to masticate and by teaching them the principles of dental hygiene.

A limited number of student dental nurses are appointed by the government every year. The maximum capacity of the training school is 40. The fact that hundreds of applications are received makes it possible to maintain a high standard in the personnel of the service.

Having completed their training and received their certificates, usually at the hands of the minister of health, the dental nurses are sent out to various parts of the dominion to carry on their work among the school children. It should be mentioned here that the problem of providing for the dental treatment of the school children in New Zealand is rendered difficult by the manner in which the population is distributed, about half being concentrated in the metropolitan and urban areas, and the remainder widely distributed throughout the rural districts, since New Zealand is primarily a farming country.

The principle has been adopted of providing regular and systematic treatment over a period of years to a limited number of children, gradually extending to new districts as a larger staff becomes available from the training school in Wellington. It is found that, working on this basis, one dental nurse can successfully undertake the care of a group of about 650 children, clinics being established at suitable centers where children up to this number can be attended to. In organizing the work, schools and school classes are adopted

as the units in preference to age groups. This makes the organization simpler, as it is so much easier to deal with classes as a whole; and, for all practical purposes, the school classes correspond sufficiently closely with the age groups.

No treatment is undertaken without the written consent of the parents, but this is forthcoming in practically all cases. The only children who are eligible for treatment, in the first instance, that is, for the initial cleaning up of the mouth, are the infant children who are in the preparatory classes, as it is considered essential that treatment begin at as early an age as possible. Whenever circumstances permit, children of preschool age are also accepted in limited numbers. The mouths of these children are made clean and healthy by such fillings, extractions and prophylactic treatments as may be necessary. The nurses interest the children in correct diet and in the use of the toothbrush, and leaflets on these subjects are given to them to take home. Parents are invited to attend on the occasion of the first examination, with the object of enlisting their interest and coöperation. Regular reëxamination is one of the main features of the work, and the organization is based on the principle of reëxamination every 6 months of every child for whom treatment has been undertaken. This, of course, limits the number of children that one officer can deal with, but, on the other hand, the system is pro-

ductive of results which would not be forthcoming if the effort were diffused over larger numbers. The system of reëxamination every 6 months, with, of course, such further treatment as is indicated, is continued as a child passes up through the various grades of a school, until he leaves the fourth standard, which is at the age of 11 or 12. Thus, each child is kept dentally fit for approximately 6 years; after which, parents are urged to see that treatment is continued. Attention is given to dental health education throughout this period. In fact, the treatment itself is regarded as educative.

In carrying out dental treatment on a large scale, a tendency to use the forceps rather freely is sometimes noticeable, and, when dealing with children, this is liable to result in undue sacrifice of deciduous teeth. This tendency is bound to creep in unless the number of patients to each operator is limited. The following figures, based on the statistics of the New Zealand school dental service, show the effect of such limitation of numbers: For every 100 fillings performed, the number of teeth extracted is 37; and of every 100 fillings, 62 are in deciduous teeth.

# PUBLIC HEALTH NURSING\*

New York Offers Social Hygiene Course for Public Health Nurses and Social Workers—Even with the existing inadequate reporting of the venereal diseases the figures show that 1 per cent of the population, or 1,227,000 individuals, are at a specified time under care for syphilis and gonorrhea. These figures do not account for any of the large number of unreported, unrecognized, and untreated cases. Interesting studies published by Dr. Nels Nelson of Massachusetts in 1930 show that over a period of 8 years in 42 states, syphilis exceeded scarlet fever by 35,000 cases, diphtheria by 390,000 cases and in 21 states exceeded tuberculosis by 78,000 cases. There is certainly a challenge to health workers in these figures.

Social Hygiene includes the preventive medicine problems of syphilis and gonococcus infections (popularly known as the venereal diseases); sex character education; activities for the protection of youth from moral hazards, especially those tending toward sex delinquency; measures directed against commercialized prostitution; and other activities designed to preserve and protect the social and physical health of the family.—(*Report of the New York State Health Commission.*)

Social Hygiene is a family problem and as such is the concern of every public health nurse. No one can escape the responsibility and all need the accurate knowledge acquired by study and the practical information supplied through discussion of the application of definite principles to specific case problems.

The New York State Department of Health through its divisions of social hygiene and public health nursing is offering a practical course in social hygiene to the public health nurses of the state. Beginning in October, monthly conferences or discussion

groups will be held in about 30 cities over the state.

The course will consist of assigned readings for each month requiring about 3 hours, the theoretical solution of actual problems dealing with cases or situations requiring another 3 hours' preparation for the 2-hour monthly conference.

Even in the three lessons on syphilis, congenital syphilis and gonorrhea, the case study method is used rather than the academic method of just learning facts.

The two lessons on sex education will be very interesting, as there are such wide differences of viewpoint on this subject, and these conferences are certain to be very lively.

Courses of study in child hygiene and mental hygiene are being planned for the next two years.

While every effort is being made by public health officials to maintain adequate public health nursing service, staffs are being reduced in many places. It behooves every public health nurse to make herself indispensable to her community and organization if she hopes to retain her job when curtailment is the order of the day. There is no better job insurance than continuous education which gives one a deeper understanding of family and community needs. At no time in the history of nursing has there been a more urgent need for well informed nurses. The problems in almost every home are more serious and more numerous than under usual circumstances, and require a resourcefulness only to be found in well informed workers. Public health nurses need the inspiration derived from study and from the discussion of mutual problems more than ever before, as their daily contacts with depressing situations strain their physical, mental and spiritual resources to the limit.

**A Famous School to Close**—The last class of probationers has been admitted to the New York City Hospital School of Nursing. An order signed by Dr. J. G. William Greeff, Commissioner of the Department of Hospitals, New York City, closes the school to further students.

The reasoning of the Commissioner is clear. More graduates were not needed, for New York has many unemployed graduate nurses. The lack of some of the acute services so necessary to the proper training of students necessitated sending the students to other schools for affiliation for a full half of their 3-year course. Careful study revealed the fact that a graduate staff for the acute wards and an attendant service for the chronic wards would be more economical than the student service burdened with the heavy load of affiliations.

This school, guided by nurses noted for their leadership, has an alumnae association adorned with illustrious names. "A pioneer in its inception, it is equally a pioneer in its manner of closing, for again it is responding to the impetus of a social vision of no mean order."—*A Famous School to Close, Am. J. Nurs., XXXII, 8:871 (Aug.), 1932.*

**A California County Health Officer Pleads for Public Health Nursing in the Schools**—In a letter to the San Luis Obispo City School Board, Dr. Allen F. Gillihan, County Health Officer, pleads so logically and convincingly for public health nurses and health development work in the public schools, that it may be an inspiration to other health workers who are facing a similar situation. It follows in part:

It has just been brought to my attention that you are considering the discontinuance of the health development work in the city schools of San Luis Obispo, and, as your health officer, I am addressing you in order to lay calmly before you the vital importance of such work in modern education.

The work in education of the past few

centuries has well proved that a child can neither grasp nor retain instruction unless he is in normal condition; that is, unless his brain is able to function naturally. . . . It would be equally as foolish to use the modern high-pressure expensive methods of education on an undernourished child as it would be to punish him for inattention. Such efforts would be as futile as an attempt to fill a reservoir when the water escaped through leaks almost as quickly as the high-pressure engineering method endeavored to fill it.

By the state school law, school budgets must be based upon the average daily attendance of the previous year. It would seem only reasonable in order to keep attendance up to the mark that very close attention be given to reducing the number of absentees and repeaters as much as possible. Cursory examination into causes of absentees from school, and repeaters in school work, would show that sickness is the most frequent actual cause, as well as a most threadbare excuse; so naturally endeavor should be made to keep sickness down.

Modern higher technical education provides for the training of public health nurses, and the State Department of Education tests the training and ability of each applicant before allowing her to do health and development work in the schools. Although it may at times be difficult to secure a suitable nurse, still there is no lack of competent workers in this field.

Your department must now have available records of the city schools for a number of years. If you will have a tabulation made from these records showing the proportion of absentees each year, your work would quickly show the value of such a nurse in keeping up the average daily attendance on which to calculate the budget for the next year. . . .

The work of public health nurses should at all times be supervised and directed by a person having training, experience, and knowledge of relative values in public health; the results of the nurse's work should be evaluated by the same standards. . . .

The financial depression that is now sweeping the country has resulted in much unemployment. That this will result in undernourishment of your younger school children is but natural. Undernourishment in young school children means poor school work and many repeaters at the end of the school term. This wastage of much money could have been saved by searching out and correcting undernourishment tendencies at its very beginning. In some parts of the United States school nursing service has been discontinued after

having been established for several years, and even at this early date the folly of such action has been demonstrated. In the June *Survey* an article by John K. and Margaret A. Norton on What is Happening in the Schools, says:

"In the State of Washington many counties have given up their school nursing service. That this is a dangerous economy was shown by the increased sickness among school children."

The California State school law places the responsibility for the control of communicable diseases in the school directly on the shoulders of the school board.

In the event of an epidemic being introduced into a school, it should be found that the school authorities had neglected to protect themselves under the State Regulation, the responsibility would be theirs.

. . . The efficient and well trained school nurse, by requiring that every absentee from school must pass through her hands before being allowed to return to school, can effectually block such an outbreak. Furthermore, she could find a child with defective vision, secure glasses for him and feel satisfied when she ascertains that his school work promptly improves and the threatened unsatisfactory school work is prevented, and school money is saved from having to be spent on repeating a year's work. Undernourishment could be discovered at its very onset, the cause searched

out and corrected. . . . In all sincerity I must say that it is not in a spirit of antagonism that I am warning your board of this unwise and dangerous economy of discontinuing your health and development work, but entirely from an honest desire to help you. . . .

Health of School Child Comes First,

Canadian Nurse Given Opportunity to Study Abroad—In recognition of the comprehensive program of maternal welfare carried on by the Victorian Order of Nurses for Canada, the Rockefeller Foundation has extended to Elizabeth Smellie, its Chief Superintendent, an invitation to visit a number of European countries within the next few months for the purpose of observing and studying conditions of maternal welfare there.

Miss Smellie was to sail from New York early in September, visiting among other countries, England, Denmark, Austria, Germany, and Italy, returning to Canada about the middle of December.

## EDUCATION AND PUBLICITY\*

High School Radio Speaking Contest—Senior high schools in Westchester County, N. Y., participated in an 800-word radio speaking contest as part of the 1932 Early Diagnosis Campaign program of the Health Education Committee, Westchester Tuberculosis and Public Health Association. James A. Tobey, Dr.P.H., Chairman; Ethel M. Hendriksen, Director of Health Education. In Yonkers the same plan

was featured by the Yonkers Tuberculosis and Health Association.

Fifteen senior high schools, one-third of the number invited, were represented on the radio program. Nine boys and 6 girls gave 5-minute radio talks in 5 programs on consecutive days over Station WCOH, Yonkers. Three talks were featured with two musical numbers intervening, supplied by high school students, making up half-hour programs.

Two talks judged the most effective were broadcast later over Station WRNY, New York City. The awards

\* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

consisted of a certificate of merit in two colors, featuring Robert Koch in his laboratory. Each student winning recognition in his own school or appearing over the radio received this certificate especially inscribed and signed. Sample of the certificate will be sent on receipt of 3 cents postage. Westchester Tuberculosis and Public Health Association, 8 Church Street, White Plains, N. Y.

The radio station was so pleased with the feature that the contest will be repeated to aid the Christmas Seal sale.

**Adapting Health Education to Human Beings**—"Our health education," says Dr. Iago Galdston, speaking on "The Psychophysics of Health Education," is based on the assumption that the individual to whom we address ourselves is passive, is in fact "like an empty vessel, biding time until we come to pour into it what quantity of knowledge and wisdom we see fit." Dr. Galdston's thesis is that health education should be based on a recognition of the dynamic nature of the human being.

If I may be permitted a rather crude analogy to make my point clear, the task of the educator appreciating the dynamic nature of his pupil is as that of a batsman facing a pitched ball, in contrast to, say, a billiard player who seeks to pocket a billiard ball. In the case of the billiard player, he has a bat called a cue; he has a stationary billiard ball and a fixed objective. The billiard player is primarily concerned with the setting of his cue, and with the direction of his thrust, knowing that he can count on the ball to remain stationary until he is ready to shoot, knowing also that the pocket will not shift and that his billiard table is smooth and free of obstacles.

The batsman, however, is part of a dynamic system. The ball he must strike at comes to him with a speed of its own, with a curvature and flight which he must take into consideration. There is an important time element in his performance. He must swing his bat with all factors taken into consideration. Failing of this, he will fan the air, or else make an ineffective if not defeating gesture.

Fortunately, for the batsman as for the educator, the momentum of their respective objects is not capricious and not infinitely variable. Pitched balls, as individuals, fall into a definite and determinable set of categories. And, dropping our analogy, we know that the momentum and progress of the individual's life follow a pattern which is common to the average being.

The quotation is from a paper delivered at the meeting of the National Tuberculosis Association June 7, 1932, and will appear in the association's Transactions as well as in "The Nation's Schools."

**Problems in Dramatizing Scientific Material**—In anticipation of the clinic on radio plays scheduled for the American Public Health Association convention, October 24-27, 1932, we review here comments received on the series of radio plays about the "Conquest of Disease" broadcast by the Detroit Department of Health and the Detroit Dairy Council. The series was described in this department in the June, 1932, issue.

The questions raised by the critics are of the sort likely to arise in other experiments with the dramatic method of presenting health information and some advance thinking about them may help to point up the discussion at Washington.

The first comment deals with the relation of dramatic interest to health teaching. One critic finds that the themes of these plays center around events and situations that teach no health lesson.

The theme should involve some measure beneficial to the listener and which he can carry out for himself; I mean, getting vaccinated, having a physical examination, or seeing that his children have a tuberculin test, etc.; or it should develop a feeling of friendship and a desire to aid in the advancement of some existing institution.

To make my points more specific, consider two of the playlets—take the one on Jenner and the one on Yellow Fever. In the one on Jenner the dominant theme is the unpleasant

conditions of Merry England, while for Walter Reed, it is the ingratitude of Congress and the hard boiledness of newspaper men. In all the talks vital matters pertaining to health improvement are definitely subordinated to dramatic emotional appeal from any angle that presents itself.

Opposed to this criticism is the belief that listener interest is in inverse ratio to the amount of propaganda with which a play is loaded; that building a theme around an obvious moral defeats its own end.

A dramatization of public health which stimulates interest in the subject in general provides an opening wedge for getting persons who would otherwise pay no attention to the subject, to listen later to straight talks.

The next point has to do with scientific accuracy and the dramatic form of presentation. In the series under discussion errors of two kinds were noted. The first are historical, such as several wrong dates, credit for medical discoveries attributed to the wrong persons, and fictitious accounts of events supposed to have occurred in the lives of famous physicians. Has the dramatist the right to distort facts in this way in the interest of his plot? The critic thinks not.

The second set of inaccuracies cited relate to disease and its conquests. The critic says:

The world is not all but free of diphtheria. The bite of a mad dog never was a sure fatality. Persons suffering from hydrophobia do not bark like a dog nor mew like a cat nor do they attempt to bite other persons. A mad animal is not insane. Antitoxin does not contain poison. This apparently is a confusion of toxin-antitoxin with diphtheria antitoxin.

Are errors like these inevitable accompaniments of the process of fitting characters and events into a dramatic form of presentation? If so, is the play an unsuitable method for health education? Or can errors expressed in the conversation of characters in a play be condoned on the ground that radio listeners take in so little detail that these mistakes are not impressed on their minds?

Another interesting point raised:

These radio dramas present scientific discoveries as if they were made in a tense, melodramatic atmosphere with inspiration as their dominant fount.

It is important to sound health education, the writer believes, that the public should realize that medical discoveries are of slow growth. The most casual listener to some of these melodramatic plays gets the impression that one man in one big moment discovered how to prevent or cure a disease.

Are the interests of the dramatist and the scientist then incompatible? This last question, perhaps, puts the whole controversy in a nutshell.

A final criticism relates to the advertising feature of the broadcast:

If the continuity finished with a statement that these dramas were sponsored by the Detroit Dairy Council whose business it was to increase milk consumption, I would have no objection, but in each case the milk is dragged in by the hair of the head and tied up to the stirring drama.

The general impression of the commentator just quoted is quite favorable:

In general, I think they are fine. I do not think they are too melodramatic for the purpose intended. . . . I am not one of those who are so afraid of departing a hair's breadth from fact that they are afraid to say anything with a living spark in it. . . . I think the Radiodramas are good because the final effect must be a stimulation of interest in public health procedure on the part of those who would never otherwise know anything whatever about the subject.

Another comment is favorable:

I feel that a real contribution to health education has been made. . . . For the most part it seems to me that the broadcasts are fairly accurate for radio purposes. While there is something of the melodrama in some of these broadcasts . . . to attract and hold attention it was necessary to make them fairly striking.

Dr. Henry F. Vaughan, Health Department, Detroit, has a few more sets of the Radiodramas which can be sent to health workers upon request.

Mary P. Connolly, Director of Health Education of the Detroit Department of Health, to whom the above discussion was submitted, writes:

We have little defense to make of the material presented and we know that some of the criticisms are warranted, especially those which draw attention to such expressions as an "insane animal." These inaccuracies were corrected in the material before it was presented but unfortunately the original copy was used when it was mimeographed.

Relative to the first comment, I should say that I believe it is assumed that drama should not be used for propaganda. If the purpose of drama is to provide a healthful escape from reality, we, as health educators, will not help the cause of mental hygiene by using the drama for propaganda. As to the time element to which reference is made, drama, as we understand it, should deal with character portrayal and not with events arrayed in chronological order.

We know that dramas are crude in spots; on the other hand, we know that many Detroiters learned from them that science has its heroes and a great part of the public knows only of heroes of battle or of sport.

It is quite true that the man who wrote these dramas took liberties with the material given him for their construction, but it will be difficult to find an historical drama of which the same criticism cannot be made.

Perhaps the most significant result of this presentation was the distribution of more than 200,000 pieces of literature, requests which came from listeners. The literature dealt with the selection of an adequate diet on a reduced income and was distributed at a time when most of us were worried about thousands of families who were facing a second winter on a very curtailed income or were receiving public relief. The science of nutrition came to their aid in selecting food for their families.

M. S. R.

Reader's Friend or Foe—Ralph P. Bridgman, Director of the National Council of Parent Education, was the principal speaker at the session of the National Conference of Social Work at Philadelphia at which "Mental Hygiene Literature: Reader's Friend or Foe" was discussed. Mr. Bridgman criticised a lot of the present-day literature giving advice on the raising of children, and

counseled parents to get from their daily experience the understanding and insight needed which cannot be secured from books. He apparently does not think much of most of the mental hygiene books that have come off the presses in recent years. "They are generally written," he said, "in a detached and scientific vein as though parents were another of our national phenomena. Parents are not scientific."

To illustrate his point the speaker quoted from a number of mental hygiene books which are widely distributed. One of these was the statement of George Bernard Shaw that the world needs parents fit for parenthood. Mr. Bridgman further declared that most such books are written by spinsters or unmarried teachers, and he suggested that "perhaps the best mental hygiene literature of the future will be fiction."

Mr. Bridgman's strictures on educational material on mental hygiene were seconded by Dr. Gerald H. J. Pearson, psychiatrist at the Philadelphia Child Guidance Clinic, who said "it is a fetish of the American people that knowledge solves all problems." He said further that "reading books is a kind of soothing syrup taken by those who do not know themselves."

A keynote of the discussion was that we have been rather hard on parents in this matter of teaching them how to bring up their children and that psychiatrists are beginning to change their attitude toward parents. They are beginning to consider them more as human beings, like the rest of us. This point was stressed again and again in Mr. Bridgman's paper, which quoted copiously from many recent books.

Dr. Pearson seemed to disagree with the notion that parents can learn how to train their children by reading books, many of which deal with extreme forms of misconduct in a way that does little if any good to the parents who read them. He compared this with the mis-

take of discussing the later stages of tuberculosis with individuals who are only beginning to show the initial symptoms. Mental hygiene books should not, for example, discuss perversions for the benefit of the average reader. He interpreted the wide popularity of this literature as a phase of civilization, and considered that the prevalence of interest in this literature was due to the desire of people with personal problems to look to such literature for authority as they heretofore looked to the church and tradition.

Mrs. Cecile Pilpel of the American Child Study Association in her discussion of Mr. Bridgman's paper spoke of two types of mental hygiene literature: (1) that addressed to the general reader interested in personality development, and (2) books on parent-child relationships read by church, school, and study groups. She declared that such literature should not be concerned solely with emotional aspects of mental hygiene, and expressed the confidence that a better and more rational, good sense type of literature will emerge in the future.

Miss Christine Robb of the Institute for Child Guidance, New York City, also criticised some of the current mental hygiene literature, illustrating one of her points by referring to the extreme case of a parent who had followed John Watson's books literally, to her detriment and that of her children. She deplored the fact that pseudo-scientists were writing mental hygiene books today because our clinicians and mental hygiene educators were not. She thought that mental hygiene literature was peculiarly dependent upon its manner of presentation for its good or bad results.

Dr. Benjamin C. Gruenberg said that mental hygiene is now in the stage of the discoveries of physical pathology, although we are beginning to emerge from this stage and are thinking in terms of mental hygiene as a way of life.

He spoke of a transition from the negative to the positive side of mental hygiene education. He did not think much of books on how to behave, and spoke of the need of holding from time to time a clinic on mental hygiene books, referring to the present meeting as a good beginning.—Paul O. Komora.

**"Lobby" Sessions**—The Washington program is rich and varied—for the health educator and for health workers in all fields. Equally important will be the "lobby" sessions—the exchange of ideas and experiences with individuals and small groups. "What is on your mind?" "What question do you want answered?" Ask these questions—and give your own as well and the conference will start.

*And bring your questions to Education and Publicity Headquarters. We want to know what they are.*

**Ask for Education About Milk**—Said the report of the Committee on Milk of the Conference of State and Provincial Health Authorities (June 2, 1932):

The local health officers of committees in which any considerable percentage of the market milk is still sold raw are urged to use an educational approach. . . .

Furthermore, the dairy industry, through the agency of such an organization as the National Dairy Council, could with advantage inaugurate a persistent radio program which would combine a campaign for adequate milk consumption with one for the encouragement of the use of pasteurized milk only. If the National Dairy Council or other dairy organization undertakes such a radio program, the U. S. Public Health Service and the various state and city health departments should assist in furnishing the necessary educational material.

The report also outlined educational work with the milk producer, allotting parts of the effort to the health and agricultural departments. In *Public Health Reports*, Washington. Aug. 12, 1932.

## BOOKS AND REPORTS

Towards National Health, or Health and Hygiene in England from Roman to Victorian Times—By J. Anthony Delmege, O.B.E., With a Foreword by Sir Thomas Legge, C.B.E. New York: Macmillan, 1932. 234 pp. Price, \$6.50.

Two unusual books on the history of medicine have appeared during the past year, *Man and Medicine*, by Sigerist, reviewed in our issue of July, and the one whose title heads this review. Unlike as they are in many ways, both go back to fundamentals.

Delmege points out in his preface that the ground he covers has been strangely neglected and he knows of no work which considers it, which seems to be true. He has covered the history of medicine thoroughly though briefly from something like 10,000 B.C. to 1875, when the great Public Health Act was passed. Except for the ancient historical features the history is largely of medicine in England.

Vaughan, in his autobiography, makes the statement that if history were more carefully read there would not be so many alleged discoveries announced. It is interesting, therefore, to find descriptions and see illustrations of terracotta pipes from the Island of Crete dating 3000 to 1800 B.C. These pipes are said to have been beautifully made and finished, fitted with cemented joints and laid on concrete beds.

The Egyptians naturally had evolved a high degree of hygiene, though they were helpless in face of epidemics. Moses had the Egyptian type of education and his ideas were unquestionably founded upon that. The Mosaic laws gave us the first definite legal codes which were enforced upon an entire nation. From this time on the author traces in various nations the develop-

ment of hygiene in the earliest civilizations, describes the sewage disposal of Rome, and the bath houses and baths in Roman countries.

An unpleasant note, though true, shows that the physicians in the great plagues of the 17th century did not live up to the standards which have always marked the medical profession. They fled with the rich to the country and left the poor people to suffer; but here and there stand out those wonderful figures of whom the world must always be proud, such as the vicar of Eyam who stayed by his parish until the plague exhausted itself after 13 months and left only himself and 29 others out of an original 350 inhabitants.

The great reformers, like Howard, Sedgwick, Simon and Southwood Smith, and the great physicians Jenner and Sydenham with many others are mentioned in interesting sketches. Again the truth of what Vaughan said is demonstrated when we read what Howard said about the plague—that cleanliness, fresh air, adequate diet, and separation would save many more lives than the parade of medicines in the apothecary's shop.

The story of the gin drinking craze which lasted for 25 years is also described. One can hardly help wishing that the author had been a little more full in his stories, but it must be said that practically nothing of value has been omitted. We have a most interestingly written story covering a vast length of time.

The book is well illustrated with excellent portraits obtained from authentic sources. The printing and make-up are exceptionally good, though the number of illustrations and their size have compelled the use of a paper which is heavy and glazed. MAZÛCK P. RAVENEL

**Health and Home Nursing**—By George Margaretta Douglas. New York: Putnam, 1932. 383 pp. Price, \$2.50.

In all nursing schools nurses sooner or later study the history of nursing because—

The origin of our various activities, the spirit animating the founder of a profession, and the long struggle toward an ideal as revealed by a search into the past—these vivify and ennoble the most prosaic labors, clarify their relation to all else that humanity is doing, and give to workers an unfailing inspiration in the consciousness of being one part of a great whole.

It is logical and fitting then that high school and college girls studying home nursing as they are doing more and more every year should have this insight into the past also, and perhaps they need it more as they are not apt to have Dock and Stewart's revised *A Short History of Nursing* readily available.

Miss Douglas devotes four chapters of her book to the concern for health among prehistoric people, and those in the ancient and medieval worlds, leading up to health and nursing in the world today. Then she has a fine chapter on the care of the baby and preschool child—laying the foundations of health in the years when most can be done, when there is a chance to prevent a great deal of illness.

The rest of the book is devoted to topics usually treated in books of this kind, such as symptoms of illness, making a comfortable bed, and the like. She gives a little more of the philosophy of home care and gets in a little more of the inspirational side of nursing than usual. The last chapter, which deals with occupational therapy and its effect on mental hygiene, is new.

The Questions and Activities at the end of each chapter are original and thought provoking. There is a full and carefully chosen list of References and

Suggested Readings, also, after each chapter, and a complete Bibliography, an appendix and a good index at the end of the book.

There are a few typographical errors, but the book is attractively printed, well illustrated and simply written—it makes very interesting reading. It is scientifically sound, practical, and up-to-date. It is recommended highly.

EVA F. MACDOUGALL

**Medical Men in the American Revolution 1775-1783.** *The Army Medical Bulletin No. 25*—By Louis C. Duncan, Lieut. Colonel, U. S. Army, Retired. Medical Field Service School, Carlisle Barracks, Pennsylvania, 1931. 414 pp.

In this bulletin Colonel Duncan analyzes and discusses the available official and unofficial data dealing with the medical men and the medical activities of the American Army during the American Revolution. The story is especially well told, interesting, and readable. The author has drawn delightful pen pictures of such noted men as Church, Morgan, Shippen, Rush, and many others. He discusses dispassionately their successes and failures against a background of ever changing political and military conditions.

It appears that typhus was the most prevalent disease among the American troops, and that the intestinal diseases and smallpox also exacted a terrible toll in lives and health. The attempts to control smallpox by inoculation are graphically described. The author estimates from his data that 70,000 men died of disease during the entire period of the war, or an average of 10,000 a year. He also estimates that 10,000 died as the result of battle injuries.

*Medical Men in the American Revolution* is published as a Government bulletin. The text is divided into 25 chapters and 2 appendixes. Explanatory notes and a biography are placed at

the end of each chapter. It is a welcome and very much worthwhile addition to the literature on the history of medicine.

GEORGE C. DUNHAM

**Accidents, Neuroses and Compensation**—By Dr. James H. Huddleson. Foreword by Dr. J. Ramsay Hunt. Baltimore: Williams & Wilkins, 1932. 256 pp. Price, \$4.00.

Because of the advent of Workmen's Compensation Laws and the World War, traumatic neuroses have assumed increasing importance, especially as related to industrial accident work.

This excellent scientific treatise includes a consideration of historical points; etiology; classification and symptomatology; structural pathology; post-traumatic psychoses, psychopathies, and malingering; specificity between situation and syndrome; evolution, duration, and prognosis; differential diagnosis; treatment; compensation; and prophylaxis.

There is an excellent bibliography of approximately 500 international references. A useful feature of the book is a summary at the end of each chapter. Case histories are wisely used to illustrate various principles.

The author has some very definite ideas concerning compensation:

In brief, if the awarding of money for traumatic neuroses cannot be legally and finally abolished, then it should be given in a single sum at the earliest possible moment, in an amount ranging from \$50 to \$500. Actual verdicts in personal injury suits are too tardy in time and too liberal in amount. The postponement of a final cash award destroys its curative properties. Continuous payments possess questionable socio-economic merit and generally less than no therapeutic value.

Regarding prophylaxis, Dr. Huddleson states:

If, as Wechsler says, "a neurosis is the penalty one may pay for growing up," then traumatic neuroses are among the penalties incurred by society through hyperindustrialization and depersonalization. Without being

obliged to alter main trends, civilization is bound to apply correctives. . . . Quick resumption of occupation is strongly prophylactic in the face of sudden fright and little injury. Patients with cerebral injuries must be kept in bed long enough to preclude postconcussion neuroses.

This technical and highly specialized work deserves a place in the library of every industrial physician, where it will eventually prove its usefulness as an important reference volume.

C. O. SAPPINGTON

**Vitamins: A Survey of Present Knowledge.** *Medical Research Council Special Report Series, No. 167.* London: Published by H. M. Stationery Office, 1932. Price, 6s, 6d. net.

In 1931 we had a very complete and excellent review of "The Vitamins" from the Pickett-Thompson Research Laboratory, also the second edition of "The Vitamins," by Sherman and Smith. Now comes the present volume, which is complete and thorough. While the book is vouched for by the Medical Research Council, there is a special Committee upon Accessory Food Factors. The auspices under which this extensive report is issued places it practically beyond criticism.

The book opens with an historical introduction of 14 pages, one of which is given up to charts. We believe this to be the most exact history we have examined, and much needed in view of the claims which have been made by certain persons. Each of the vitamins is then taken up in turn, and an especial chapter is given to "Vitamins and Dental Tissues," which takes in the work done by May Mellanby.

Useful as the story of the vitamins is of itself, for the general reader, the last third, approximately, of the book will be more interesting and of more practical use to the average physician, considering as it does, "Some Nutritional As-

pects of Cow's Milk with Special Reference to Vitamins," "Vitamins and Human Diets," to which 42 pages are given, and "Vitamins in Diet of Mother and Infant." These really treat of the application of our knowledge of the vitamins as given in the first two-thirds of the volume.

The illustrations are abundant and excellent, as are also the tables. Under each vitamin, foodstuffs are listed giving the relative amount of that particular vitamin in them, together with the references from which they are taken. At the end there are 25 pages of references.

Appendix I, Table XXI, gives a list of foodstuffs, requiring 9 pages, with the relative amount which each contains of all of the vitamins, A, D, E, B<sub>1</sub>, B<sub>2</sub>, B, and C. Appendix II gives the report of the Conference on Vitamin Standards, held in London in 1931. There is a good index.

With this book alone, there is no reason for anyone to lack knowledge concerning the accessory food factors. It shows the careful preparation and exactness which has been so characteristic of the publications of the Medical Research Council of England.

MAZÛCK P. RAVENEL

### Manual of Public Health Nursing—

*Prepared by The National Organization for Public Health Nursing. New York: Macmillan (2d ed.), 1932. 253 pp. Price, \$1.50.*

Every public health nurse whether working alone or on a staff should find this *Manual* a safe guide and ready reference. It contains procedures and technics scientifically worked out, and it holds the cream of all the policies, procedures and technic the world over.

The standards set up by N.O.P.H.N. in this book are wide in scope and general in character leaving room for each individual organization to modify them to meet its needs. The material is

rightly divided into two parts, "Organization and Administration," and "Nursing Procedures and Techniques," making it clear in its meaning and easy to refer to.

RUBY ROGERS

**Human Sterilization. The History of the Sexual Sterilization Movement—***By J. H. Landman. New York: Macmillan, 1932. 341 pp. Price, \$4.00.*

Chapter I is concerned with the general eugenics movement and the systems which may be used to restrict the multiplication of socially undesirable individuals. The author believes that since segregation of catogenic individuals has failed to eliminate them from the race, the more effective method of human sterilization of the socially inadequate individuals should be practised.

By means of statistical evidence given in Chapter II, the author acquaints one with the extent and cost of the mentally diseased and incompetent individuals in the United States. The succeeding chapters deal with the problem of human sterilization, including a history of human sterilization in the United States; the legal status of human sterilization laws; types of mentally diseased and mentally deficient people; and the classification of the inheritance of psychotic traits and of mental deficiency. The various types of human sterilization operations are listed, including the relatively new biological method. Possible physiological and mental effects of sterilization are discussed. The legal status of human sterilization operations is treated concisely. In Appendices A to J, statistical data in regard to sterilization statutes, motives for sterilization operations, records, and fees are given.

The author directs attention to the fact that cases of dementia praecox and manic-depressive insanity are most frequent in institutions, and that very few recover. For this reason he considers

it important that therapy and legislation should be concerned first with these cases.

The work can be recommended for its fund of information concerning a controversial question. It is well documented, and must serve a useful purpose.

NEWELL R. ZIEGLER

**Official Proceedings of the 37th Annual Convention of the American Society of Municipal Engineering, Held at Pittsburgh, Pennsylvania, October, 1931—*St. Louis: American Society of Municipal Engineers, 1932.*** 855 pp. Price, \$7.50.

This volume presents in 27 chapters the matters dealt with by municipal engineers, city officials, and others at the 37th Annual Convention in Pittsburgh. Certain chapter headings indicate the types of municipal problems receiving discussion in this 5-day meeting—city planning, air ports, traffic control, municipal financing, paving construction, and maintenance. Of particular interest to sanitary engineers and sanitarians are chapters V, VI, and VII, dealing with water works, refuse disposal, and sewerage and sanitation.

In a paper on taste and odor removal, Baylis calls attention to various methods in use. Among other things he says "So far as is known there is practically no taste producing compound likely to be present in water that cannot be removed by activated carbon." The powdered forms seem to be most satisfactory. D. E. Davis describes several modern zeolite plants in his paper on zeolite in water softening. Detailed cost data are given, particularly on the plant at Sewickley, Pa. In a discussion of lime-soda water softening, Porter deplores the lack of attention to this important problem. He points out that less than 10 per cent of the water supplies in the United States needing hardness removal are softened.

Chapter VI covers refuse disposal and

reviews prevailing tendencies in incineration. Sewerage and sanitation are dealt with in Chapter VII. Specific subjects discussed include sewer maintenance, mechanical handling of sludge, sewage and trade wastes treatment, and lime-chlorine treatment.

E. S. TISDALE

**Diseases of the Coronary Arteries (Myocarditis)—*By Don C. Sutton, M.D., and Harold Lueth, M.D. (Illus.) St. Louis: Mosby, 1932.*** 164 pp. Price, \$5.00.

The authors, with a wide knowledge of the literature and a clear insight into the broad and extensive theoretical aspects of the subject, have made this work one that should be of practical application to the specialist in cardiology, but most particularly to the man in the general practice of medicine.

The book has three outstanding features—the practical nature of the subject matter presented; the clearness of expression, and particularly the distinctive and lucid description of clinical signs and symptoms; and the emphasis that is placed upon the physical signs and symptoms. By students in cardiology and those in the practice of medicine, the work should receive recognition and wide acceptance.

In recent years much emphasis has been placed upon electrocardiography by those writing upon the subject of the various phases of heart disease. The electrocardiograph is an expensive apparatus and one that is available to only a small percentage of those practicing medicine. The authors properly give recognition to this refinement as an aid to diagnosis and prognosis. They also and properly emphasize that even with the electrocardiographic interpretation, reliance for the diagnosis under given conditions must often be placed unhesitatingly upon the clinical diagnosis; that is, physical signs and symptoms. They repeatedly call attention to the dangers

of relying entirely upon an electrocardiographic curve in the diagnosis of either coronary or myocardial disease.

There is one criticism to be offered. In recording the leucocyte count, the authors fail to give the findings that are of the utmost importance—the differential percentages, and an evaluation of the young, or immature forms of the polymorphonuclear neutrophils. The total white cell count, which is the only leucocyte count recorded, is only an index of resistance on the part of the patient to an infection. It is not an index to the presence of an infection. The differential leucocyte count, which is the most reliable guide to the presence of an acute pyogenic infection, should always be recorded wherever the leucocyte picture is under consideration, and with this there should be an evaluation as to the young or immature forms of the polymorphonuclear neutrophils.

M. PINSON NEAL

**Cancer. What Everybody Should Know About It—By James A. Tobey, D.P.H. Introduction by Joseph Colt Bloodgood, M.D., and H. L. Mencken. New York: Knopf, 1932. 313 pp. Price, \$3.00.**

There has long been a need for a popular work on cancer, one in which the style is simple and the subject presented in a manner not too repellent.

For many years the only volume which in any sense met this need was the volume written by an Englishman, Charles P. Childe, entitled "The Control of a Scourge, or How Cancer is Curable." But this book is now out of date in many of its aspects, though it is still valuable because of its breadth of vision and the admirable style in which it is written. It is practically unknown in this country except among those interested in the educational phases of the cancer question.

For us especially a work is needed from the American viewpoint, particu-

larly one giving full information about methods of control employed in America. This the author has accomplished in an exceedingly satisfactory manner, and has used his material well. The interesting records of the past have been introduced, and form an introduction to the whole subject of cancer.

The writer then turns to the occurrence of cancer in famous people, that is, famous people in whom cancer was acknowledged as a cause of death. There are many not on his lists whose death certificates or obituary notices mask under the diagnosis of heart failure or pneumonia the fact that their end was really due to cancer. True, this phase of falsification of death certificates is passing, but there are numerous examples of it still known to every consultant.

The types, locations, diagnosis, and treatment of cancer are then taken up. Obviously, as the writer is not a physician, the medical side is not presented in a highly technical fashion, but sufficient is said to enable people with the more common varieties of cancer to realize their situation and consult a physician, provided they desire to do so. There still remains a strange hesitancy on the part of intelligent individuals to take this step which places upon them the responsibility of accepting an operation or radiation treatment, so long as they can conceal, by some process of mental inhibition, the exact nature of their disease from themselves and from their families, and there are still many who turn up at last in desperate condition, asking for help when no help can be given. Education does little for such people.

On the other hand, there are those whose lives are rendered burdensome by the fear, and usually an unnecessary fear, of the disease. This development of a cancer phobia has resulted in some criticism of the organizations whose object it is to provide public education.

In many instances this criticism is loudest from members of the medical profession, who directly benefit in so far as their ability to cure cancer cases is dependent upon the education which these agencies offer. The members of the medical profession, however, are still too set upon cure, and not upon prevention. They do not realize that these neurotics, if they did not have a cancer phobia, would have some other kind of phobia, and would still throng their offices and ask for a diagnosis. A little kindly interest in such people and a careful physical examination will remove their fears. If the neurosis recurs, another examination will give them a period of mental rest—all this with the very slightest expenditure of time and energy on the part of the physician. It is strange that such a situation exists in these days.

The chapter on treatment leads obviously to the subject of radium and X-rays, and one of the best chapters is that in which the work of Roentgen and of the Curies and their remarkable discoveries are outlined. An excellent warning is given as to the necessity for long and painstaking research which will surely be necessary before an effective general cure may be discovered, and the conditions under which any suggested cure must be studied. Some of the loudly advertised "cures" are treated in detail.

The question of the increase in cancer is intelligently discussed, and a sane position taken on that phase of the cancer question, concerning which it is easy to become emotional.

A most original portion of the book is that discussing quack cures. It should be read by everyone, for every physician knows how prone people are, when they hear that a friend or a relative has cancer, to recommend some extraordinary quack, and place the family physician in an embarrassing situation. If he is unable to cure the patient, why

should not the patient go somewhere, they ask, and take something, often at a high price, which may possibly do some good? The fact that it never has and never will do any good seems to be no deterrent to the lay mind. This problem leads to the discussion of cults, of the method of selecting a good physician, as contrasted with the quack, and finally an excellent review of the rise of the educational movement in cancer in this country and in Europe.

In the last chapter there is a summary in the form of a group of cancer maxims which compresses in a few sentences the essential facts a layman should keep in mind.

The volume is illustrated with an excellent series of charts, many of them drawn from the publications of the American Society for the Control of Cancer, and a useful bibliography is appended for those who wish to read further on the subject. Altogether the volume is well written, excellently printed, and admirably covers the ground which the author intended it to do.

FRANCIS CARTER WOOD

**Report on Chronic Disease in New Jersey—*Department of Institutions and Agencies, Trenton, New Jersey, May, 1932.***

The problem of chronic disease is an especially difficult one. We have before us a report made in accordance with a joint resolution of the New Jersey Legislature in 1931, which gives every evidence of expert study as well as compilation.

It shows that 1 person in every 650 residents—a total of 6,000 to 7,500 chronically ill patients—is under the care of various agencies. There were 14,000 deaths from cancer in 1931. In 1880, only 2.2 per cent of the deaths were due to cancer, but there has been a steady rise to 10 per cent in 1930. Practically the same thing is true of

heart disease, to which 12.2 per cent of all deaths were due in 1920, while in 1930, the percentage had risen to 21.7.

Another point of great interest to all health workers is the shift in the age of those chronically ill, which seems undoubtedly due to public health work, which saves the younger. In 1880, 18.5 per cent of the population in New Jersey were 45 years or over, while 21.1 per cent of the deaths occurred in those 60 or over. In 1930, the percentage for the first group was 23.1, while the death rate in the latter group had risen to 44.1, and the deaths of children under 5, which made up 39.1 per cent of the total

in 1880, had fallen to 12.1 per cent in 1930.

This excellent report considers also the facilities for treating and housing chronic cases, and excellent programs are suggested.

Crippled children come in for due consideration, both as regards causation and subsequent care. Infantile paralysis, as would be expected, stands first as the cause of crippling, with tuberculosis second.

This report can be commended to all health workers as well as to those interested in health conditions.

## A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

**Milk Production Standards**—Committee (State and Provincial Health Authorities) recommendations in reference to the misuse of the term "natural" for raw milk; short-time pasteurization; recombined milk; and other problems of dairy and creamery supervision are published.

ANON. Report of Committee on Milk. Pub. Health Rep. 47, 33:1683 (Aug. 12), 1932.

**Preventing Postvaccinal Encephalitis**—Encephalitis, which occasionally follows vaccination, may be prevented by employing a suitable technic, performing vaccinations in infancy, and preferably after immunization with toxoid. This is a highly important paper.

ARMSTRONG, C. Postvaccination Encephalitis. Pub. Health Rep. 47, 30:1553 (July 22), 1932.

**European Public Health**—As public authorities in Europe lay increasing stress on adequate treatment as a basis for public health, the private practitioner of medicine more and more is drawn into close relation with the government. Where the coöperation is best, the material position of the physician has not suffered.

BOUDREAU, F. G. Relation of Private Medical Practice to Public Health in Europe. J. A. M. A. 99, 9:720 (Aug. 27), 1932.

**British Prenatal Hygiene Practice**—Some of the reasons why antenatal care sometimes fails to prevent mortality are set forth in candid detail. The final conclusion is that much that passes for prenatal care is too irregular, too infrequent, too ill organized and perfunctory to deserve the name, and can never do anything but bring preventive midwifery to ill deserved disrepute. When

the English call a spade a spade, they do it with vengeance.

BROWNE, F. J. Antenatal Care and Maternal Mortality. Lancet 223, 5679:1 (July 2), 1932.

**Child Labor vs. Child Health**—The possibilities in our present economic and industrial conditions for the increase in the employment of children to the detriment of future public health is discussed, as is the need for preventive measures.

DINWIDDIE, C. Child Labor: The Enemy of Child Health. Pub. Health Nurs. 24, 9:461 (Sept.), 1932.

**Variable Streptococci**—Presenting evidence that a streptococcus, a rod-shaped spore producer, and a filterable form are different phases in the life history of the same organism recovered from cases of epidemic encephalitis.

EVANS, A. C. The Metamorphosis of Streptococci into Spore-Bearing Rods and into Filterable Forms. Pub. Health Rep. 47, 34:1723 (Aug. 19), 1932.

**Maternal Mortality**—A questionnaire study of maternal deaths in New York State is reported upon. Less than half the deaths were associated with live births; abortion was a factor in a fifth of all deaths; a third of the patients had previous illnesses which may have affected the outcome. These are some of the findings.

GARDINER, E. M. Maternal Mortality—Outline of Method of Study. Child Health Bull. 8, 5:146 (Sept.), 1932.

**Irradiated Milk**—Despite its failure to measure up in antirachitic units according to the standard rat tests, irradiated milk was found in practice to be highly potent in preventing rickets. This naturally leads to a question of the reliability of accepted tests.

HESS, A. F., and LEWIS, J. M. Milk Irradiated by the Carbon Arc Lamp. J. A. M. A. 99, 8:647 (Aug. 20), 1932.

**State and Local Health Units—**“A state department of health should be prepared to assist county health departments through financial assistance, establishment of standards for personnel, administrative guidance and technical service.” This is the first of several eminently reasonable conclusions ending this worthwhile contribution to administrative practice.

MUSTARD, H. S., and SHARP, W. K., JR. Service of State to Local Health Departments. Pub. Health Rep. 47, 31:1601 (July 29), 1932.

**Pasteurization in England—**In this discussion advocating general pasteurization, the statement is made that, although England lags behind other countries in this matter, in London more than 90 per cent of the milk is pasteurized.

ORR, T. Is Pasteurization the Solution of the Milk Problem? Pub. Health 45, 11:326 (Aug.), 1932.

**High School Health Education—**In Lynn (Mass.) a highly successful health education program was formulated and carried out. This paper has the merit of telling, not what should be done, but what was done and how.

STEPHENS, E. The Three-Year Health Education Study in the Lynn English High School. New Eng. J. Med. 207, 6:263 (Aug. 11), 1932.

**Training Health Educators—**The training in the basic sciences, hygiene and pedagogy that should be required of the school health educator is set forth in convincing detail.

TURNER, C. E. Training for Health Education. Pub. Health Nurs. 24, 9:486 (Sept.), 1932.

**American Public Health—**This brilliant summary of the newer movements in health administration designed for British ears will prove just as worthwhile for home consumption.

WINSLOW, C.-E. A. Current Tendencies in American Public Health. J. Roy. San. Inst. 53, 2:62 (Aug.), 1932.

## NEWS FROM THE FIELD

*It will be appreciated if readers will send to this department such items of news interest concerning public health activities as they consider suitable.*

### 100 YEARS AGO

**A**N ordinance creating a board of health in Trenton, N. J., dated July 3, 1832, was recently found by the city clerk. This was 55 years before local boards of health were required by law in New Jersey. The board appears not to have been appointed for a definite length of time, but one could be appointed in case of need and it could dissolve itself when its work was done. The board was authorized to procure and circulate advice concerning the danger of infectious and contagious diseases and in time of epidemic to “take

such measures as they may deem best calculated to arrest its progress and render its ravages less destructive,” and it was its duty to “make daily reports of progress of the disease and the measures which they have adopted.”

### ATHENS USES ANCIENT AQUEDUCT

**W**HEN Greeks and Romans builded, it was for permanency. The new water works for the City of Athens, constructed under the direction of an American, Richard M. Merriman, of Bethlehem, Pa., includes in its system the ancient Hadrian Aqueduct, a fifteen mile tunnel through the Plains of Attica.

This aqueduct, apparently, was originally constructed during the second

century A.D. It was used for 1200 years, but was then abandoned for some unknown reason. It has now been cleaned and renovated, and through it flows water for the citizens of Athens who for centuries have scrimped along on one and one-half gallons of water a day for all purposes.

The water works themselves, as explained in an article by Oren Arnold in the *Water Works Journal* for April, 1932, occupy the site of the historic Battle of Marathon. Marathon Dam was constructed in 5 years at a cost of \$12,500,000. This, however, was 19 miles from Athens. The Parnes Divide was crossed by an 8-mile tunnel and the Hadrian Aqueduct utilized for the remainder of the distance.

It was necessary to combat malaria constantly during the construction period. Living quarters were doubly screened, stagnant water drained and oiled, and minnows from Italy put into the new lake.—*Health News*, New York State, Aug. 15, 1932.

#### ROAD DUST PREVENTION

**A**MONG recent developments in chemical science, designed to promote public comfort, health, and safety, is the discovery of a better method for the prevention of dust on gravel highways. Every year road dust exacts a large toll in the form of accidents, due to dust clouds at curves, intersections, and other dangerous points.

To correct these conditions, many communities are using a comparatively new method of treatment, known as the calcium chloride treatment. Calcium chloride is supplied for road dust prevention in the form of small white flakes, which when spread over the surface of the road begin immediately to absorb moisture from the air, continuing the process until the surface appears to have had a light rain. Unlike rain, however, this moisture remains for weeks and in some cases months, binding the

loose dust into a moist, smooth, durable surface.—*Public Safety*, 6, 9:14 (Sept.), 1932.

#### PERSONALS

BERNARD C. ROLOFF, formerly Director of Health Education of the Chicago Department of Health, is the new Executive Secretary of the American Mouth Health Association, of Minneapolis.

MAJOR EDGAR ERSKINE HUME, M.D., DR.P.H., F.A.P.H.A., has been appointed Librarian of the Army Medical Library—Surgeon General's Library—of Washington, D. C. This institution, the largest medical library in the world, was founded by Surgeon John S. Billings, who also planned the Johns Hopkins Hospital Library and the New York Public Library, and was President of the American Public Health Association in 1879–1880.

HARRY S. MUSTARD, M.D., F.A.P.H.A., of the Tennessee State Department of Health, has been selected to take charge of the new public health district recently created in Baltimore which was placed in operation on September 15.

DR. VERDO T. WEBB has been appointed Health Officer of Little Rock, Ark., succeeding Dr. Charles R. Moon, who resigned.

DR. WILLIAM T. SHORT, of Stonington, Ill., has been appointed District Health Superintendent of the Illinois State Department of Health. He succeeds Dr. Frank P. Auld, of Shelbyville.

DR. FRANK V. NEWCOMER succeeds the late Dr. Edward M. Boggess, of Elwood, Ind., as member of the Elwood City Board of Health.

DR. THOMAS J. MCKEAN, of Montpelier, was recently appointed to succeed the late Dr. Marion A. Emshwiller as Health Officer of Montpelier, Ind.

## The Health of the People in a Year of Depression\*

LOUIS I. DUBLIN, Ph.D., F.A.P.H.A., *Life Member*

*Third Vice President and Statistician Metropolitan Life Insurance Company,  
New York, N. Y.*

IT is the duty and pleasure of your retiring President to report first on the state of the Association. We have closed a very successful year. On the first of September, there were 4,742 members and Fellows on our books, representing professional health workers in every state of the union, every province in the Dominion, and the two neighboring republics of Cuba and Mexico, to our south. In spite of hard economic conditions, the like of which none of us can remember, our membership has held up to within 25 of the number on our rolls at the last Annual Meeting when we reached our maximum. We have elected or reinstated 612 members and Fellows during the year, and I am particularly pleased to report that we now have 69 Life Members. I hope this movement which means so much to the Association will continue to grow.

Our finances likewise are in good shape. Our income from membership dues, from the JOURNAL and other publications, and from the Annual Meeting this year can now be safely estimated as in excess of \$71,000. These are the items of fixed income and show a decline of about \$22,000 as compared with last year. Our contingent income which is for surveys, grants from Foundations and others, for specific purposes, has decreased by about \$25,000 this year. Our total income will, therefore, be about \$47,000 less than last year. But to offset that, we have been very careful to cut our expenses and there is every indication that we shall close the calendar year with a small surplus. Most other voluntary organizations, I am sorry to say, are running

---

\* Presidential Address delivered before the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

into larger or smaller deficits. Thanks to the excellent management of our Executive Secretary and the guidance of our Treasurer, we have put our resources where they will do the most good. Great credit is due the staff who have accepted serious salary reductions without murmur and have, under conditions which must have been very difficult, carried on their work with all the energy and enthusiasm which have always characterized them and which have made the Association the great force for good that it is.

I report to you also a year of real achievement in the promotion of the public health. The four standing committees of the Association have functioned well under trying conditions. The Committee on Administrative Practice has continued its operations, spreading its gospel of high standards and efficient health service throughout the land. Although the Committee on Fellowship and Membership was very much hampered by lack of financial support, it has, as I have already said, produced a record of which we can be proud. I am particularly pleased to refer to the splendid work of the Committee on Meetings and Publications. You must all of you have been greatly impressed with the extent and character of the program which the committee has prepared. Some 300 papers have been provided, covering every phase of the public health problem and fully 100 of them are by speakers who have never before appeared on our programs. It is in this way that the Association profits from new blood and extends its influence into new areas. The Committee on Research and Standards, in spite of a far-reaching and constructive program of work has, unfortunately, been compelled to go slowly. I wish we could have put larger resources at the disposal of this excellent committee, but the condition of our budget made that impossible. Nevertheless, I am convinced that the four committees are functioning well. Their activities add to the knowledge and practice of good public health work; stimulate the membership to greater achievement; and increase the technical efficiency of all of us.

I cannot, however, leave this subject without referring to a few projects which to my mind are of preëminent importance. The first is the Health Conservation Contest which we have been conducting in conjunction with the Chamber of Commerce of the United States. This continues to be the most dramatic and practical service of the Association. The contest now reaches directly over 260 cities in 45 states with an aggregate population of close to 30 millions, or about one-quarter of the total population of the country. These cities have directly profited by the knowledge gained through the surveys, by the advice and guidance of our field staff, and by the widespread dis-

semination of good public health information in the community. Indirectly, many more cities with large populations have been favorably affected; for it is impossible to conduct a contest of the magnitude of ours without having its influence spread far beyond the limits of the cities enrolled.

The record of the contest is replete with valuable results. It is significant that the cities enrolled take part in the contest year after year and show improvement in their consecutive scores. More than 90 per cent of all the cities which were entered more than once, received higher scores last year than in any preceding year, in spite of the fact that 50 points were taken off the possible maximum. The average score among the 36 cities which won or received honorable mention in 1931 was approximately 88 per cent of our reasonable standards, and the average expenditure to attain this was only \$1.71 per capita. The average score for all cities in the contest for 1931 was 650, as compared with an average score of 542 for 1929. Probably the most important result is the very real interest in the public health movement which the contest has evoked among prominent business men of the country. From 2,000 to 3,000 such leaders have become actively interested in community health and have in this way become allies and supporters of local health officers. Our contest has convinced these influential citizens that by improving the public health, they can at the same time benefit the financial standing of their communities. The Health Contest has passed the experimental stage and we may all look forward to its expansion until it covers virtually the whole country.

The second activity which, I believe, calls for special mention is the publication of the revised edition of *Community Health Organization*. This was prepared under the supervision of the Sub-Committee on Community Health Organization of the Committee on Administrative Practice and has been most carefully edited by Prof. Ira V. Hiscock. We are grateful to the Commonwealth Fund for doing a beautiful printing job and for distributing the volume. Every health officer in the country now has available to him in brief compass a well written and practical treatise on the most approved health practices. The problems of personnel, of administration, of budgeting, are all considered clearly and soundly. It is altogether a monumental work. I hope it will find its way into the hands of every health officer, not only in the United States and Canada, but in all other countries where public health administration is conducted along similar lines. It will certainly help to raise standards of technical health service to a very high level.

I wish it were possible to refer in the same detail to other valuable activities of the Association, such as the revision of the *Appraisal Form for Rural Health Work* made by Dr. Bishop's Committee, the revision of our *Standard Methods for the Examination of Water and Sewage* made by our Committee on Standard Methods in coöperation with the American Water Works Association, the operations of the sub-Committee on Training and Personnel under the leadership of Professor Turner, the excellent work done by our large Western Branch and the organization of the Southern Branch. I am compelled, however, to limit myself to the high spots and will ask those who are associated with other valuable services to forgive me. I can only say that in turning the Association over to Dr. Ferrell I am delighted to report that all is well. The Association has never been better organized, or possessed a more enthusiastic membership, or had a clearer conception of its service, or awaited a more brilliant future.

#### THE HEALTH OF THE COUNTRY

It is particularly gratifying to note the very favorable health conditions that have prevailed throughout the United States and Canada during the last year. By and large, the health of the people as measured by the reports of sickness and deaths has never been better, in spite of the fact that this is the third year of serious economic depression. With possibly 10 millions unemployed and with the general state of mind clouded with many perplexities and uncertainties, the health of our communities has apparently stood up well.

Sickness and death rates are either the lowest in the history of the country or very close to it. Early in the year, the Surgeon-General of the U. S. Public Health Service reported that the death rate in 82 large cities had been 11.8 per 1,000 in 1931, as compared with 11.9 the year before. Since then, morbidity and mortality have continued each month at an extremely low level. For the first 37 weeks of 1932, General Cumming reports a death rate of 11.2 for 85 large cities, as compared with 12.1 for the same period in 1931. The industrial life insurance companies, whose experience is also indicative of what is transpiring in the general population, are likewise reporting the lowest mortality rates among their policy holders. In the largest of these companies, the cumulative experience up to the end of September this year was about 3 per cent lower than last year which was an excellent health year. The best feature of this picture is the fact that there is no evidence as yet that the depression has adversely affected the physical resistance of the people.

Infant mortality, deaths from the communicable diseases of chil-

dren, tuberculosis, and pneumonia—all of which we have in the past, either rightfully or wrongfully, associated with the level of the standard of living—have continued to decline this year. Tuberculosis and pneumonia are remarkable in this regard, showing rates respectively about 7 and 17 per cent lower than last year. I should, however, point out that our records throw no light on the mental health of the people which must be anything but good. Nor can I avoid the fear that, should present conditions continue, we will soon become aware of the consequences of malnutrition of children in terms of disease and mortality records. To date, I am glad to say there are only a few authentic observations pointing in this direction. The available facts, especially on mortality, may give all of us who are concerned with the public health, encouragement, satisfaction and pride.

I have speculated as to what underlies the satisfactory health picture, and will consider briefly some of the factors which are probably involved in the situation. There is first the favorable meteorological conditions which have prevailed. The weather was propitious both last winter and this summer, and as a result many people were able to lead an active outdoor life. In addition, there were no serious epidemics of disease. Influenza was less widespread this year than it has been recently; the cases that occurred were much less virulent and resulted in fewer attacks of pneumonia and other fatal complications. I would mention also changes in the mode of life which have been forced on many people during the depression and which probably contributed to better health habits. There has undoubtedly been less over-drinking and over-feeding. People have been less exposed to the hazards of machinery. Unemployment, much against their will, has brought them rest and leisure, more sunshine, and opportunities for outdoor exercise, all of which play a part in keeping people well.

But I am inclined to believe that the most important factor in the situation is the continued and effective functioning of the health departments, the medical profession, and the social service agencies. These deserve our highest praise. They have all carried their heavy burdens cheerfully and have performed their tasks in a highly efficient manner. The organizations which have grown up during the last 30 years, the health departments, the medical clinics and the hospitals, have waited for just this opportunity to demonstrate their usefulness. When people could no longer pay for private medical care, they received much free treatment from doctors. Everywhere they found the public departments of health, the private welfare socie-

ties, the hospitals and dispensaries ready and happy to serve them. I have no doubt at all that these agencies have helped to keep up the public morale, have carried on essential work and have tided many a family over a very difficult period. Especially valuable has been the educational work they have conducted for many years prior to the depression and which is now serving as a reservoir of knowledge upon which the public continues to draw. I can report with enthusiasm on the operations of the public health and social agencies during the last few years.

But my enthusiasm must be somewhat tempered. I realize that these organizations have gone through a very trying time. Under pressure of the economic stringency, states and cities and philanthropic societies have been forced to give very serious consideration to economies in their budgets and many health activities have suffered in consequence.

#### RECENT REDUCTIONS IN HEALTH BUDGETS

At the beginning of this year when the first rumblings of reduced budgets and of curtailed staffs became audible, the Association launched an inquiry among the health officers of the country to determine the extent to which the financial stringency was affecting them. We received 200 replies. Over 50 per cent had already suffered a budget cut. These varied in amount but averaged 7.4 per cent. The cities, particularly the larger ones, suffered more than the counties or states. But apart from a few outstanding instances, the reductions were small and were easily absorbed either through a slight reduction in the salary scale of the staff or through a contraction of the less important activities. More ominous was the fact that 56 health officers reported that further cuts were in prospect.

To bring our knowledge up to date and to determine, if possible, how serious the situation is at the moment, I sent out another questionnaire about a month ago to the same group of health officers. We have already received 345 replies from 40 states, 165 counties, and 140 cities. Our material is fairly representative, covering health departments in every part of the country. There has been no reduction of the health budget in 1932 in 24 states, 48 counties, and 45 cities, although in many of these, there had been a cut in the preceding year. In the remaining 228 offices, there were reductions varying all the way from less than 5 per cent as a minimum to a maximum where the department has been entirely eliminated. The average reduction in these 228 departments was about 11 per cent. Again we find that the cities, particularly those with more than 500,000

population, suffered most. Detroit, Pittsburgh, and Baltimore were most severely affected. Toledo, Akron, Norfolk, and Houston, received big cuts. The reductions in a few of the states were particularly large. In North Carolina, a general reduction of 33 1/3 per cent was made. In Florida and in New Jersey, the reductions were about 20 per cent, and in Ohio, 17 per cent. New York State fortunately suffered no loss but rather received an increase in its budget. A number of county health organizations, including Coffee County, Ga., McCurtain County, Okla., Greenwood County, Kans., were discontinued. In Anderson County, S. C., a budget of \$91,000 in 1931 was cut to \$7,000 in 1932. In Orange County, Calif., and in Marion County, Ore., the budgets were reduced about one-third. A large number of health officers continued to report that further cuts were in contemplation.

TABLE I

## SURVEY OF EXPENDITURES BY PUBLIC HEALTH DEPARTMENTS IN 1932

	<i>Total</i>	<i>States</i>	<i>Counties</i>	<i>Cities</i>
Total number of questionnaires returned..	345	40	165	140
Number of health officers supplying budget data .....	304	33	144	127
Total amount of budgets reported for 1931 .....	\$50,647,431	\$17,258,682	\$2,638,017	\$30,750,732
Total amount of budgets reported for 1932 .....	47,011,886	17,290,615	2,357,892	27,363,379
Net increase (+) or decrease (—) in 1932 .....	—3,635,545	+31,933	—280,125	—3,387,353
Per capita Health Office expenditure in 1931 .....		.18	.42	1.13
Per capita Health Office expenditure in 1932 .....		.18	.37	.99
Number of health officers reporting budget reductions in 1932.....	228	16	117	95
Total amount of budget reduction in Departments reporting reductions in 1932 .....	\$4,678,135	\$882,634	\$341,281	\$3,454,220
Percentage of reduction in above Departments .....	11.1	8.4	16.7	11.6
Number of health officers reporting salary reductions in 1932.....	135	11	68	56
Number of health officers reporting reduction of one or more activities in 1932....	147	18	73	56
Number of health officers anticipating further cuts in 1932.....	53	11	24	18
Personnel dropped during 1931 and 1932				
Total .....	1,242	222	153	867
Physicians and dentists.....	237	20	24	193
Nurses .....	362	52	66	244
Others .....	643	150	63	430

Needless to say, such drastic changes required rapid and thoroughgoing adjustments. In 135 departments, salaries were reduced in varying amounts, and in many other instances a loss of

personnel was also made necessary by the reduced resources. Our record is obviously incomplete but it shows that in these 345 departments there was a total loss of well over 1200 persons, including physicians and nurses. Detroit alone lost over 100 employees, and Baltimore dropped 93 from its staff. It is furthermore significant that in the adjustment of activities, certain branches of health work suffered more than others. Child welfare and public health nursing, for example, seemed to have borne the brunt of the reductions. On the other hand, tuberculosis activities were, for the most part, disturbed hardly at all. It would be interesting to know what determined this peculiar policy in so many of the communities. Was it not because those in charge of tuberculosis work were better able to convince their communities of the importance of their efforts?

The present tendency to cut public health expenditures is of grave concern to all interested in the nation's welfare. Throughout the year, your Association has done everything possible to maintain health budgets. Your President has addressed many meetings and has written hundreds of letters on your behalf urging local leaders in both business and welfare work to keep the health facilities of their communities intact. Nevertheless, as we have seen, reductions have occurred and in many places, they have been large enough to do serious damage to the organizations. Nothing can be more certain than that in the past the health departments of the country have not been over-extended. Health officers and health workers generally have been notoriously underpaid. Health departments have been understaffed and their budgets do not, therefore, lend themselves to deflation. We know, for example, that the average expenditure for all health services both public and private in a group of 175 cities, for which reasonably accurate information was available through the Health Conservation Contest last year, was only \$1.12 per capita per annum. Even in the 36 cities which won the highest awards, the average expenditure was \$1.71. On the other hand, 15 per cent of the cities spent less than \$.50 per capita; 17 per cent spent between \$.50 and \$.75; and 13 per cent between \$.75 and \$1. Only a little more than one-half spent over \$1 per capita, including both official and voluntary public health agencies. These figures are for cities which have shown real interest in public health work and their expenditures are undoubtedly higher than for cities in general.

In the counties, the budgetary situation has been much worse. Only a quarter of the 2,000 counties in the United States have anything like adequate or full-time health service. Even in the counties where there has been some attempt at organization, the average

expenditure was only \$.38 in spite of the fact that county health service, by its very nature, calls for larger per capita costs than do cities. Only a very few counties show expenditures of \$1 or more. The appropriations of the states necessarily supplement those of the municipalities and counties. Nevertheless, state health appropriations are still very small. In 1930 they averaged only \$.13 per capita, ranging from less than \$.01 in Nebraska to \$.35 per capita in Delaware.

Altogether, we are spending something like 120 million dollars, or about \$1 per capita for health work of all kinds whether administered by official or by private agencies. This is the amount which in the heyday of public expenditure was allocated for this important service. On its very face, this amount is only a fraction of what is needed. The modest estimates prepared by our Committee on Administrative Practice call for appropriations of \$2.50 per capita if a well rounded program is to be maintained. In the counties, where health work is more difficult to conduct because of the distances to be covered, the expenditure to be adequate should be nearer \$3 per capita. In other words, our expenditures in the past have never reached more than from one-half to one-third of what we could spend profitably. There has been no wild development and no tendency to grow too fast. Very few communities have ever spent enough to derive the great benefits that sanitary science and modern medicine have made possible. It is with meager amounts indeed, that genuine achievements in disease control have been accomplished. We are still very far from where we can afford to cut down on public health work.

What we need in the present emergency more than anything else is to spread among the people, and especially among the leaders, a true concept of the importance of public health in the social economy of the nation. This is obviously your duty. You, who represent the strength and leadership of the nation's health workers, must go back to your communities and broadcast the message I have just given you. Sound the alarm and arouse the public to a realization of the situation that is threatening. It is especially desirable that you win the support of your local medical societies, the chambers of commerce, the business men's groups generally, the women's clubs, and particularly the press. Make them all realize that the maintenance of the public health at high levels is vital to the public welfare. Better times are bound to come. The present emergency which has necessitated the paring and cutting of budgets will undoubtedly pass. The most important question for us is whether the leaders of our states and cities will then restore health appropriations because they appreciate

the basic position of the health movement in modern society. It is essential that this concept be clearly understood, and I propose to clarify it in the final section of my address.

#### HEALTH AS A FACTOR IN SOCIAL ECONOMY

Little do most of us appreciate the influence which the public health movement has had on our times. It has made a different world for us to live in. Sixty years ago, when Pasteur and Koch were making their astounding discoveries, life was still very cheap. The death rate even in our country was about 20 per 1,000 according to our best estimates. Of the children born in any year, 20 per cent were dead before their first birthday. Diphtheria and the other diseases of childhood decimated them during their toddler years. Typhoid fever and malaria laid their heavy toll on adolescents, and tuberculosis was a constant menace to young adults, breaking up families and causing much poverty and misery. The expectation of life under the conditions then prevailing was just over 40 years. It was indeed a fortunate family that did not show the marks of premature bereavement; no wonder people were so keenly aware of health hazards!

How different is the picture today. The expectation of life of the new-born is now 60 and not 40 years. The infant mortality is not 20 per cent, but only a little more than 6. Children need not get diphtheria, nor young people typhoid fever; and if parents and teachers are watchful, young men and women need not suffer from tuberculosis. The heavy hand of disease and the possibility of premature death has been lifted from the families of the country, permitting them to work out their destinies within the limits of their native abilities. These changes have revolutionized our social economy. They have made it possible to build up our cities into enormous aggregations of people. The extensive urbanization of our population would have been impossible but for our increased knowledge of the nature of the communicable diseases and how best to control them. We ordinarily completely overlook our dependence on sanitation and the many other activities of our health services.

The public health movement has added enormously to our wealth and capacity to live well. For a number of years I have attempted to demonstrate that life and health are our greatest assets. In *The Money Value of a Man*, Dr. Lotka and I have compiled figures which show the commuted values of net future earnings of people in various income classes and at various ages of life. Our calculations indicate that the money value of our people transcends all other forms of

capital and the aggregate is, in fact, 5 times as great as the total of all of our material resources. These figures and our mode of approach are coming more and more into general use, not only here but in other parts of the world. Professor Winslow especially has performed a valuable service in applying the tables to various places, including the cities of Syracuse and New York where extensive public health projects have been conducted in recent years. He has shown that the reductions in death rates from a few of the diseases which undoubtedly respond to organized effort have resulted in enormous savings of capital values. In New York City, for example, an annual expenditure of less than 15 million dollars for health promotion of all sorts by public and private agencies has produced an aggregate saving of over 200 million dollars annually. In Syracuse, the mortality reductions for a limited number of age groups and for a few diseases represent a saving of 3 million dollars a year accruing from a total health budget of less than \$500,000. Dr. Shepard of San Francisco has in a similar manner calculated the savings which have been or could be accomplished in some of our western states through the strengthening of their public health services. Dr. Pollock has computed the money losses resulting from mental disease. Others, I am confident, will be tempted to utilize the figures which we have made available, to show the wide disparity between the savings resulting from competent public health work and the low cost at which these savings are made possible.

I need not amplify this thesis here except to say that the public must become more generally aware of the great economic value which human beings possess and the enormous losses which communities sustain when workers are thrown out of employment because of illness or when premature death deprives families of their support. This has not been an academic discussion; nor is our computation one of paper values. Our findings have perfectly definite and practical implications. When a death from typhoid fever occurs, it is not only the family that suffers the loss of many thousands of dollars. This loss is soon distributed over the whole community. Reduced taxes come into the public treasury. The community is often forced to maintain the dependents of the deceased, and very often must assume the added cost of providing over long periods for neglected children and disrupted homes. We do not ordinarily recognize the solidarity between the community and the individuals that compose it. I would not stress the money value of life except that such evaluation helps to make us aware of our mutual interdependence and the significance of each individual to the modern state.

If we were then motivated by only the most selfish considerations, we would be very careful to maintain our public health services at the very height of their efficiency even during periods of depression. It is obviously penny wise and pound foolish to do anything else. After all, public health work as it is conducted even in the best departments, costs very little. From \$2 to \$3 per capita would give most places excellent service, worth many times that amount. No community even at present is so poor that it cannot afford to safeguard the life of its citizens. No city, county, or state can run the grave risk of wrecking the public health organization which has been built up over many years. This is certainly no time to drive trained public health servants out of the profession; nor to drop well tried and useful activities. Unless we are very careful, we may through these attempts at false economy let loose forces which will undermine our very capacity for speedy economic recovery. I hate to think what it would mean in cold dollars and cents if we were suddenly confronted with epidemics of typhoid fever, of smallpox, or of diphtheria. The health protection of our communities is like a dyke which prevents the ravages of a flood. Once our defenses are weakened, increased sickness and death would make economic recovery all the more difficult. If governmental economy is necessary (and everyone is agreed that it is), there are many types of activity less vital that should be curtailed first—not one that threatens life itself.

But I am loath to rest my argument for public health service on economic grounds alone. The knowledge and practice of good public health have enriched every phase of modern life. They have raised the very quality of our civilization. The control of disease has banished the fear of premature death and has thus added to the joy and cheerfulness of life, as is evident when we compare conditions here with those prevailing in the Orient. The reduction of physical disabilities has made life fuller, diverting energies that were formerly utilized in the struggle to live into more constructive channels. When people no longer have to fight against pestilence and plague, they have time to devote to the peaceful arts and to other creative activities. The status of the family is being changed as a result of the health movement. The family group is now kept together until the children have reached maturity. No one can possibly overestimate the significance of this to the well-being of the next generation. The survival of young children has made it possible for us to balance our population without undue childbearing, thus releasing the energy of the mother to other activities of the family and the community. Richer content has been given to social life which has rapidly filtered

down to the benefit of the individual man, the ultimate and only real unit of value.

As in the field of medicine, public health work makes no distinction between the rich and the poor, between the high and the low. The prevention like the cure of disease knows no levels. The method and spirit of this movement maintains the finest of democratic traditions and holds out the largest promise for a glorious future. It is this phase of health service that should give purpose and direction to our professional work.

Do we the health workers of America need a better creed or a greater inspiration to carry on? Ours is the great opportunity. When all the world is sick, when business falters and counsels waver, we at least know what to do. Let us be equal to the occasion! Let us maintain our high purpose to keep the people well against all odds. Our effort will help the nations weather the storm. I hope it may also show those in high places how other public services may best be conducted in a democratic government.

---

## Doctors Differ

“DOCTORS differ” is a rebuke which the profession inherited when the title of doctor was, by common custom, extended to medical practitioners. It is well known that the saying had nothing to do with medicine, but was levied against theologians, not without some deserving. But now when it is used, and that is not infrequently, it is directed against the practitioners of the medical arts. Lord Dawson has, on several occasions, resented the innuendo of this popular saying. He has pointed out, with much truth and justice, that differences of opinion in medicine, the existence of which is beyond denial, are trivial when compared with the differences which are rife among politicians, theologians, sociologists, and, we might add, biologists, and are greater only than those among the practitioners of the physical sciences. The art of medicine is among the oldest things in human culture, but the science of medicine is one of the youngest. Originally founded on magic and superstition, not unmixed with craft, fostered and developed by observation and experience, it was not till the dawn of modern history that the art of medicine began to rest on logical deductions from established evidence—which is science—and it has not yet been able to shift over completely to this more solid foundation. Medicine is still in a transitional stage. Chemistry has discarded alchemy, astronomy has forgotten astrology, but medicine still embraces the mediaeval lore which in past ages took the place of science. Much of the nomenclature still used by us does not belong to science, and the use of words, however much their meaning may be modernized, carries with it traces of the philosophy which gave rise to them.—Abstract from Address by Lord Dawson of Penn in accepting the Presidency of the British Medical Association for the centenary year. *Med. Off.*, July 30, 1932, p. 41.

# Relapsing Fever in California

GILES S. PORTER, M.D., M. DORTHY BECK, AND  
I. M. STEVENS, F.A.P.H.A.

*California State Department of Public Health, San Francisco, Calif.*

ENDEMIC focuses of relapsing fever have been reported in Colorado, Texas, and California. In 1921, Dr. Le Roy Briggs of San Francisco reported 2 cases in which the infection was contracted at Polaris on the Truckee River, California. The diagnosis of both was confirmed by the demonstration of spirochetes in the blood and both responded to treatment with neoarsphenamin. These patients had been bitten on the legs by insects. Urticarial marks on their legs and blood spots on the bedding warranted this conclusion, but no bedbugs could be found and no ticks were seen at any time during the trip.

No further evidence of relapsing fever came to the attention of the California State Department of Public Health until September, 1930, when Dr. George Stevens, Epidemiologist, Los Angeles City Department of Health, reported a case in a school teacher who had lived at Big Bear Lake during July and August. About August 1 she suddenly developed a high fever, severe headache, generalized tenderness of the muscles, and slight dizziness. This illness lasted about 5 days and the patient was well until about August 15. The case was diagnosed during her fourth relapse on September 16 and the diagnosis confirmed by finding the spirochetes in the blood smear. The patient could not recall having been bitten by any insects but had noticed a red spot on her neck which she thought might have been a bite. She had not seen any bedbugs or ticks while there.

In October, 1930, Major V. H. Cornell, Letterman General Hospital, U. S. Army, reported, through the courtesy of the Commanding Officer, a case in which the infection had been contracted at Lake Tahoe where the patient had been from July 9 until July 24. His onset was July 27. The diagnosis was established September 8 when spirochetes were demonstrated in the blood smear. He had been bitten by mosquitoes but knew of no other bites.

Early in November, 1930, Dr. J. D. Dunshee, Health Officer of Pasadena, reported a case in a young man who had been at Lake Tahoe during August. On August 25 this patient had noticed the

bite of an insect under the right ear over the jugular vein which became swollen and very painful and remained swollen for 4 days. On September 9 he became ill and his symptoms recurred at intervals over a period of 3 weeks. Spirochetes were found in blood smears taken October 28.

When the first case of the 1931 season was reported in July, 1931, the State Board of Public Health passed a resolution making relapsing fever a reportable disease. Cases other than those brought to our attention had been diagnosed and it was therefore deemed advisable to conduct an investigation to determine the incidence of relapsing fever, the focuses, the ectoparasites involved in the transmission, and the reservoirs of infection.

To date, 30 cases have been recorded. A tabulation of these is presented here.

The history of Case 25 (C.M.W.) is of interest. This patient was a member of the group conducting field studies this year in the following relapsing fever focuses: Big Bear Valley May 16 to June 4; Lake Tahoe June 8 to June 22; and Packer Lake June 23 to June 30. His duties consisted of shooting and trapping rodents, searching brush and animals for ectoparasites, and laboratory work. He returned from Packer Lake June 30, and on the evening of July 1 developed a fever, headache, generalized pains, malaise, and had a severe chill. During the night he had several chills and his fever continued. He entered the hospital July 3 with a temperature of 102° F., pains in his chest, and a severe headache. The leukocyte count was 13,100 with 89 per cent polymorphonuclears. The following day his temperature was normal. Relapsing fever was suspected because he had been working in infected areas and spirochetes were demonstrated in the blood smear taken July 4. July 5 his temperature rose to 104° and he was given 0.3 gm. of neosalvarsan. His temperature gradually became normal, but the pains in his chest persisted for several days and general weakness continued for 2 weeks. A specimen of blood taken July 4 was inoculated into white mice and the spirochetes were recovered from them.

June 25, while at Packer Lake, this patient had picked up a bag containing 5 rodents recently shot and accidentally smeared some rodent blood on his hands, on which were several open lesions, and he washed them in disinfectant as soon as possible. The pooled specimen of blood from these 5 rodents was inoculated into a white mouse and spirochetes resembling *T. recurrentis* were recovered from the mouse. He was not bitten by any insects to his knowledge nor had he during that trip found any ticks recognized as transmitters of

# CALIFORNIA STATE DEPARTMENT OF PUBLIC HEALTH

## RELAPSING FEVER—CASES REPORTED TO SEPTEMBER 20, 1932

NO. NAME	AGE SEX	ONSET	RELAPSES	SOURCE OF INFECTION	LABORATORY FINDINGS	REMARKS
1. X.	46 M	8-11, 1921	8-24, 8-30	Polaris, Placer County. Insect bite on legs 8-3	Spirochetes in blood smear 8-25 and 8-30. Citrated blood negative in monkeys and mice	Reported by Le Roy H. Briggs, M.D., J.A.M.A. 79: 941 (Sept. 16), 1922 Insect as described appeared to resemble a bedbug more than ordinary tick. Neosalvarsan given to Mr. X and Mrs. X 8-31 No neosalvarsan given
2. X.	Adult F	8-14, 1921	8-23, 8-28	Polaris, Placer County. Insect bites on legs 8-6	Spirochetes in blood smear 8-23 and 8-30 and 8-31. Citrated blood negative in monkeys and mice	
3. A.E.Y.	62 M	9-8, 1923	9-15, 9-25	Traveling by automobile in Colorado and enroute from Denver to Los Angeles County, Calif. Stayed in auto camp Lake Tahoe—Ward Creek. Insect bites	Spirochetes in blood smear 9-26	
4. La P.	Adult F	1927 or 1928	?	No examinations made	No examinations made	
5. S.	Adult F	May, 1928	?	Insect bites at Ward Creek, Lake Tahoe	Spirochetes in blood smear	Missed case with satisfactory clinical history but not confirmed by laboratory examination Detailed history not available at time of investigation in 1931 History of febrile attacks every 10 days until March, 1931 Neosalvarsan given
6. M.T.	50 F	8-1, 1930	8-15, 9-2, 9-16	Insect bite on neck 7-20, at Big Bear, San Bernardino County	Spirochetes in blood smear 9-18	
7. F.M.B.	50 F	7-5, 1930	7-18, 7-28, 8-7, 8-31	Tick bite 6-29; tick found in bed after biting	Spirochetes in blood smear 8-31	
8. J.M.	33 M	9-9, 1930	10-13, 10-28 (Dates of earlier relapses not available)	Bitten by insect under right ear on 8-25. Bite painful and swollen 4 days	Spirochetes in blood smear 10-28	History indefinite for interval in September—statement given, after 9-12 temperature recurred off and on with febrile attacks at weekly or 10-day intervals No relapse after 9-7 but neosalvarsan was administered 9-30
9. A.McR.	41 M	7-27, 1930	8-3, 8-6, 8-18, 8-28, 9-7	Patient had been at Lake Tahoe near Carnelian Bay. No insect bites noted other than mosquitoes	Spirochetes in blood smear 9-8. Blood inoculated into rats 9-8 but findings negative	Case history obtained during 1931 investigation—history incomplete
10. R.P.	20 M	6-15, 1930	?	Patient had been in mining country near Salt Lake, Utah, and while there 10,000 sheep had passed through	Spirochetes in blood smear	
11. J.B.	5 M	6-6, 1931	One relapse about 6-17	Patient had been at Big Bear, San Bernardino County, Red spots on arm but no history of insect bites	One spirochete found in blood smear 6-17; many found during first relapse	
12. J.A.	5 F	7-9, 1931	7-17, 7-23, 8-3	Patient at Big Bear from 6-28 to onset of illness. Bitten by tick a few days after arrival there	Spirochetes in blood smear 8-6. Rat inoculated with 2 c.c. blood on 8-6 was positive	Neosalvarsan given 8-6
13. J.McC.	42 M	7-10, 1931	7-18	Patient from Lake Tahoe—no history of insect bites	Blood smear positive for spirochetes 7-20	Neosalvarsan given 7-21
14. H.P.	23 F	7-15, 1931	7-23, 7-31	Bitten by an insect a day or so after arriving at Lake Tahoe 7-10	Spirochetes found in blood smear. Animal inoculations positive	Neosalvarsan given—Governess to M.L. case

15. M.L.	12	F	7-18, 1931	7-26, 7-31	Bitten several times by insects, apparently ticks, soon after arrival at Lake Tahoe on 7-10	Spirochetes in blood smear 7-29. Animal inoculations positive	Neosalvarsan given on 7-31. Later 2 ornithodoros ticks found in the cottage
16. R.D.	8	M	7-13, 1931	7-24, 8-8, 8-21, 9-1	Patient went to Lake Tahoe 6-28 and was bitten by an insect before 7-4	Spirochetes in blood smear 9-1. Animal inoculations positive	Neosalvarsan given 9-1
17. A.W.	24	M	7-24, 1931	8-9, 8-16, 8-21	Patient went to Packer Lake, Sierra County, 7-17 and returned 7-29. No history of insect bite	Spirochetes in blood smear 8-22	Neosalvarsan given 8-23
18. L.C.	12	M	8-1, 1931	8-11, 8-19	Patient at Lake Tahoe all summer. No history of insect bites but later an ornithodoros tick was found in the cottage	Spirochetes in blood smear 8-19	No relapses after 8-19—so no neosalvarsan given
19. C.B.	Adult	M	?	Four attacks at intervals of 7 to 14 days	Patient resides at Lake Tahoe. No history of insect bites	Two sets of blood smears negative	Case diagnosed on clinical history. Patient resided in area from which 5 other cases originated
20. E.B.G.	Adult	M	Latter part July, 1931	Recurring attacks until 9-1 when he consulted a physician	Patient had taken several trips into Sierras, Lake Tahoe, and Mono and Inyo Counties	State Laboratory reported blood smears positive on 9-5	Patient seen late in September
21. C.C.	52	M	7-18, 1931	?	Patient and his brother had worked at Twin Bridges, Eldorado County, and slept in a tent. Had been bitten by deer flies only, as far as they knew	Negative	Physician reported cases in 1932—records incomplete but stated typical relapsing fever and responded to arsphenamine treatment
22. G.C.	56	M	7-1, 1931	?	Same as Case No. 21—brother	Negative	Same as Case No. 21
23. F.M.	Adult	M	2-1, 1932	Eight relapses at 8-day intervals over period of 9 weeks	Owens fur farm in Big Bear	Blood smears negative	Diagnosis on clinical history
24. G.E.C.	Adult	M	4-12, 1932	None	Accidental laboratory infection	Blood smears positive 4-19, 1932. Mice inoculated 4-19	Neosalvarsan given on 4-19
25. C.M.W.	29	M	7-1, 1932	None	At Packer Lake on special relapsing fever investigation and handled bloody squirrel proven infected with relapsing fever	Blood smears positive 7-4. Mice inoculated with blood taken 7-4 were positive	Neosalvarsan given 7-5. No relapses
26. S.G.	48	F	7-5, 1932	7-17	Patient had been at Lake Tahoe since middle of June. About 10 days before onset was bitten by "brown insect"	Blood taken 7-20. Smear negative but mice inoculated same day proved positive	Neosalvarsan given 7-20
27. H.S.	38	F	July, 1932	?	Patient's source of infection given as Big Bear	?	Report just received and history incomplete
28. H.H.	10	M	8-7, 1932	Diagnosed during third relapse 8-23	Patient had been camping at Big Bear and slept on the ground on blankets. No history of insect bites	Blood smear taken 8-23 positive	History still incomplete
29. L.K.	42	M	8-27, 1932	None	Patient at Lake Tahoe from about 8-18 to 9-7	Blood taken 8-28 and inoculated into mice proved positive	Neosalvarsan given
30. D.G.	9	M	?	?	Patient resided at Big Bear	Blood taken 9-10, 1932 and inoculated into mice proved positive.	Recent case, history incomplete

relapsing fever. His laboratory accident was followed 7 days after with a proven case of relapsing fever. This seems to present evidence that his infection was contracted by direct transfer of the spirochetes from the rodent.

The staff conducting the field studies included a bacteriologist, an entomologist and two rodent hunters. All operations were confined to those 3 areas in which all of the reported cases contracted their infection. This investigation was made in collaboration with Dr. K. F. Meyer, Director of the Hooper Foundation for Medical Research, University of California Medical School, and with W. B. Herms, Professor of Entomology, University of California.

A total of 894 rodents was either trapped or shot. A field laboratory was maintained as near the shooting and trapping areas as possible and blood smears were immediately made from the heart. During 1931, whenever possible, blood was taken from the heart and inoculated into white mice. In 1932, animal inoculations were made from all rodents. Later the animals were carefully combed for ectoparasites and then autopsied. All enlarged spleens were removed for further examination.

In the first survey, during the fall of 1931, blood smears were made from each rodent and only a few blood specimens were inoculated into mice. All of these inoculations into mice proved negative but one blood smear from a chipmunk shot near Polaris on the Truckee River which showed a spirochete, and a blood smear from a squirrel killed at Packer Lake which had a number of spirochetes resembling *T. recurrentis*.

The program for this investigation in 1932 was changed so as to provide opportunity for pooling specimens of blood from several of the same species of rodents. After making blood smears from each rodent, pooled blood was inoculated into white mice. To date spirochetes have been transferred to laboratory animals from 9 chipmunks and 2 squirrels. These findings indicate that the rodents play a part in the epidemiology of relapsing fever. Whether they serve as reservoirs of infection or whether they receive their infection from the ectoparasite which also transmits the infection to man, remains to be proved.

More detailed reports will be published when the experimental work included in the special investigation has been completed.

# Oysters and Anemia<sup>\*</sup>

E. J. COULSON

*United States Bureau of Fisheries*

AND

HAROLD LEVINE AND ROE E. REMINGTON

*Laboratory of the South Carolina Food Research Commission and the  
Department of Nutrition of the Medical College of the  
State of South Carolina; Charleston, S. C.*

NUTRITIONAL anemia is known to be quite prevalent in children. The majority of cases occur between the ages of 3 months and 2½ years; however, instances of anemia in children up to 5 years are not unusual. Mackay<sup>1</sup> reports that of the infants under 12 months of age which are brought to London clinics, 45 per cent of the breast-fed and 51 per cent of the artificially fed were found to be anemic. If diets low in iron are continued after the usual weaning time, the anemia continues to become more acute. The most outstanding feature of this anemia is that it lowers the resistance of the child to infections and disease.

The two types of secondary anemia occurring most commonly in the adult are chronic hemorrhagic and chlorotic anemia. The prevalence of these is not so well known because they frequently escape recognition and treatment. According to Powers and Murphy,<sup>2</sup> liver extract is of no value in the treatment of these types of anemia, but they respond very favorably to treatment with iron.

It has recently been reported by Levine, Remington and Culp<sup>3</sup> that the oyster is unusually potent in curing the nutritional anemia developed in rats by means of a milk diet. This effect was shown by them to be due to the inorganic elements of the oyster and, further, that elements other than iron, copper, and manganese were not concerned in the regeneration of hemoglobin. Iron and copper have long been known to be present in oysters in concentrations equalled by very few foods.

In the above investigation, oysters from only one locality were used and if this finding is to have practical application in establishing the status of the oyster as an important article of food, it is necessary

<sup>\*</sup> Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting at Washington, D. C., October 25, 1932.

to know what variations exist, as to the antianemic metals, among oysters from different producing areas and at different seasons of the year, as well as to what extent nutritional effect can be correlated with chemical analysis. In the study here reported samples of oysters were collected from all important producing areas on the Atlantic and Gulf Coasts of the United States.

The samples, furnished through the courtesy of oystermen in the various localities, were shipped, iced, in the usual 1-gallon containers. The entire contents of each can, on receipt, were transferred to a large porcelain dish; evaporated to dryness on a steam bath and dried in an oven to constant weight at 80° C.; after which they were ground and preserved in glass jars. Determinations of copper and manganese (Table I) were made by the methods employed in the previous work.<sup>3</sup> Iron was determined by the Kennedy method,<sup>4</sup> care being taken to

adjust the acidity of the unknown to that of the standard. Although it is now quite generally conceded that manganese plays no part in hemoglobin building, its determination was included on account of the recent work of Orent and McCollum<sup>5</sup> on the significance of manganese in reproduction and lactation. Differences in the mineral content of the oysters from different localities will be noted from the table, those north of Maryland being lower in iron, and higher in copper than those of Maryland and states south, including the Gulf of Mexico. These differences are statistically significant and are undoubtedly due to the amounts of these metals available in the water or food of the oysters.

An examination of the values for iron and copper of the oyster, in comparison with the extended study of 120 different foods by Hodges and Peterson<sup>6</sup> and of 110 different vegetables and fruits by Stiebeling<sup>7</sup> shows that no other commonly used food except liver surpasses the oyster in the amounts of iron and copper which it furnishes to the diet by an average serving. We may therefore conclude that as a source of these two metals of blood building potency, the oyster is comparable only with liver (Table II).

TABLE II

RELATIVE IRON AND COPPER CONTENT OF SERVING PORTIONS OF SOME COMMON FOODS \*  
WHICH ARE EXCELLENT SOURCES OF IRON

	No. of Samples	Portion gm.	Iron mg.	Copper mg.
Pork liver	4	100	25.00	0.65

\* The material for this table was obtained from Hodges and Peterson<sup>6</sup> and Stiebeling.<sup>7</sup>

† Average of 43 samples from different localities analyzed by us.

In order to test the potency of oysters from different localities in blood building, samples from 14 areas in 13 states were fed to anemic rats. The anemia was produced and the animals were handled in a manner similar to that used in a preceding work.<sup>8</sup> Either 6 or 7 rats were fed on each oyster sample, the sexes being equally divided in the group of 6, 4 males being used in each group of 7. No group contained litter mates.

During the curative period, all oysters were fed at the same level, equivalent to 5 gm. of fresh oyster per rat per day. This level of oyster yielded from 0.137 mg. to 0.523 mg. of iron per day. The samples lowest in iron yielded somewhat less than the amount previously found<sup>3</sup> necessary to bring about complete recovery in 8 weeks (0.17–0.30 mg.), while the one highest in iron yielded slightly more than the amount usually considered optimum for the rat (0.50 mg.). After the first day or two the rats ate the oysters eagerly.

In addition to the 14 groups receiving oysters, 3 control groups were also fed. Two of these received milk plus iron, 1 at the highest level furnished by an oyster sample and 1 at the lowest. A third group received milk only. The 2 iron-fed groups are included in order to demonstrate that the building of hemoglobin in the oyster-fed rats is due to the supplementing of iron by another factor.

Table III shows the amounts of iron and copper furnished each rat per day through supplements, as well as the time in weeks necessary to bring about recovery, which we have placed at 14 gm. hemoglobin.<sup>3</sup> The milk furnished 0.032 mg. of Fe and 0.014 mg. Cu daily. In this table, the various oyster samples are arranged in order of descending iron content, and it will be noted that there is a definite

\* In weeks.

correlation between iron content and time of recovery, while no such relationship as to copper exists. In other words, all oysters contain an abundance of copper, and when fed at the level chosen in this study, it is iron rather than copper which fixes the rate of recovery. Rates of growth and hemoglobin response are represented graphically in Figure I.

It should be remembered in interpreting the results shown in Table III and Figure I that the dosage of 5 gm. of oysters per rat per day was purposely chosen to yield amounts of iron at or near the minimum effective level, since only in this way differences in hematopoietic potency can be quantitatively demonstrated. Therefore, the fact that the rats in 4 of the oyster groups failed to recover in the 8-week experimental period does not indicate that these oysters are not good sources of hemoglobin building material, for had they been fed at a slightly higher level, good regeneration would undoubtedly have resulted. Likewise, had the experiment been continued a few weeks longer the animals would doubtless have fully recovered. In fact, group II at the end of an additional 8 weeks of oyster feeding (same level) had an average hemoglobin content of 16.06 mg. per 100 c.c

The calorie intake of our rats was not far from 50 per day. Fresh

FIGURE I. Showing Growth and Hemoglobin Curves for Rats on Whole Milk Powder and Whole Milk Powder Plus Supplements

Groups I to XIV inclusive are the groups receiving the oyster supplements (Table III). Group XV received a supplement of 0.523 mg. iron daily. Group XVI received 0.127 mg. iron daily and group XVII received powdered milk only.

oysters yield about 0.5 calorie per gm.; hence the rats received about 5 per cent of their calorie intake in the form of oysters, and this was adequate for regeneration of hemoglobin.

### SUMMARY AND CONCLUSIONS

The results reported here show that the oyster is equalled or excelled only by liver in the amounts of iron and copper which it may furnish to the diet in an average serving. That these metals are easily available for hemoglobin production has been shown in previous work in which it was found that oysters, oyster ash (acid soluble) and a solution of iron, copper and manganese in the same quantities, fed to anemic rats, brought about hemoglobin regeneration at the same rate in all three cases. Oysters should, therefore, be efficacious in the treatment or prevention of those types of secondary anemia which respond to treatment with iron or iron plus copper. There is increasing support for the view that dietary deficiencies can best be corrected by proper selection of foods, rather than by the use of artificial concentrates or medicinal mixtures. In order to insure an adequate supply of the inorganic constituents for hemoglobin production it would seem a wise plan also to include oysters in the diet of the pernicious anemia patient in conjunction with liver extract, since it is known that liver extract is relatively low in iron.

An average serving of oysters (110 gm.) would furnish about 2 per cent of the human calorie requirement (3,000 calories), and yield about 41 per cent of the daily dietary standard for iron, stated by Sherman<sup>9</sup> to be about 15 mg.

# Child Hygiene\*

JAMES FREDERICK ROGERS, M.D., DR.P.H.

*Consultant in Hygiene and Specialist in Health Education, U. S. Office  
of Education, Department of the Interior, Washington, D. C.*

THE child passes through five periods of existence, more sharply defined than Shakespeare's seven ages of man. In each of these periods there is need of hygiene if the child is to live, and live his life to the full.

There is the prenatal period, in which, at a headlong pace, the child recapitulates in 9 months the course which his ancestors covered in as many million years and in which 98 per cent of his energy for growth is expended. It is little wonder that, throughout this first portion of his career, the new being holds his breath lest something go wrong with the marvelous multiplication and modification of his living units.

Prenatal hygiene is of great importance even if it has to do only with symptoms and signs that things are going wrong with the maternal host, but there is in addition the very serious problem of anticipating and providing amply, through the host, for every need of the unseen being so that none of the myriad bricks of the human edifice will have to be made without straw.

Besides the problem of adequate building materials for the new being there is already at this early stage the possible threat of damage or destruction by a parasite—and especially by the pale spirochete. The danger is not to be overestimated, ill judged, or considered wholesale; but it exists as a frequent menace of the period. There is also at this period the danger of serious injury from conditions to which the mother may be daily exposed in industry.

The health of the unborn child is bound up with the welfare of the mother in all its phases. It is the business of hygiene to protect the mother during this period, by laws if need be, and to make the mother aware of the needs of the child. It would introduce her to the sources of information and aid, for herself and child, in the person of the private physician, the public clinic, and the printed page.

The second phase of the child's career begins and ends in a

\* Read at a Special Session of the American Public Health Association at the Sixty-first Annual Meeting at Washington, D. C., October 26, 1932.

day. His day of birth is more beset with danger than any future day, even in our machine age, and the short journey the child must make is more fraught with peril than any later excursion of a million times the distance at a million times the speed. It is little wonder that the infant gives a gasp of relief if he escapes the birth canal by nothing worse than a tight squeeze.

Hygiene would reduce the many possible mishaps of this passage of the child from his marine to his terrestrial existence, mishaps, which, if they do not destroy him, may mar his mentality or cripple his body through all his future years. Hygiene would discover beforehand menacing mechanical conditions in the mother, or in the child himself, and take advantage of this knowledge for their safety. It would seek to improve the assistance offered by physician, midwife, or nurse during this hazardous performance.

If through good fortune or special hygienic measures the child has avoided invasion by the organism of syphilis, its fellow, the gonococcus, may be lying in wait to ruin his most precious sensory possession. Thousands of living mortals have to thank so simple a hygienic measure as the instillation of a drop of silver nitrate that they are not in an institution for the blind.

The child enters the third period of existence, his infancy, with a cry of distress at finding himself bereft of steady warmth, of ready-to-use food materials, and a relative freedom from the pest of parasites which will prey upon him through all the remaining phases of his existence.

Hygiene hears a helpless demand for more than something that will fill the infant's belly without causing colic. There is a call for everything which is needed to complete the human mechanism already so nearly finished. There is also much need for cleanliness, for warmth, for quiet, for open air, and for opportunity to stretch and kick. Fortunately we are nearly able to understand and to supply the child's needs, but this understanding and supply are not yet for every child. Hygiene has much to do in spreading its present knowledge. Scurvy is now infrequent, but gross or radioscopic signs still mark the majority of children as badly nourished.

That pearl or diamond which makes its appearance in the child's mouth at about the 6th month of this third stage of his existence, and which creates so much excitement and comment among the beholders, is likely to prove a paste diamond or an imitation pearl. The possibility of preventing such biological shoddy (which suggests inferiority in other important structures of the body) is already in sight.

Even with the most auspicious augury for physical and mental development, the infant becomes a hotbed for fission funguses and other parasites to which he is exposed. Hygiene is still a bit helpless here but it has learned much. It affords protection from dysentery and typhoid, smallpox and diphtheria. It saves many a child from tuberculosis and scarlatina, and it often delays invasion by whooping cough and measles until a relatively safer time.

The period of infancy trails off all too soon into the fourth stage, in which the child adds to his accomplishments of air breathing and the metabolism of raw materials, those of locomotion and language, and by so doing adds to the possible dangers of his existence.

The realm of the mental life now unfolds its wonders, but with perplexing problems, including the questions of his own whence and whither. He also enters into the field of social experience with its give and take, its conflicts and compromises, and the anxieties and fears, and fear of fears, which it begets. Along lines of both mental and physical unfolding he needs sympathy and direction, and his immediate guides often need assistance.

As toddler, runabout, preschool child or what-you-may-call-him, exploring the mental and physical world, and mixing more or less with his kind, there is further opportunity for adding to his experiences with parasites, macroscopic, microscopic, and invisible, common and uncommon. Thanks to hygiene the child may enter boldly into many human contacts where death or disability were once nearly certain. By vaccination and isolation hygiene has made this a much safer world for the child in the fourth stage of his existence and by better medical and nursing care it has lessened the damage which may occur to him if he does not escape infection.

Hygiene would not merely think of communicable diseases and their prevention and cure. The child is still developing and it would ask the opinion of the physician as to his present condition and future needs. Periodical examinations are, however, not sufficient. Life is a daily and hourly business and so is health. The child who appears perfect by today's examination may be damaged or dead within a week. Those in direct charge should know the few conditions which the child needs for healthy growth and should be sensitized to the signs and symptoms that things are going well or ill.

Hygiene would guide the child into the few daily practices which bear on his physical and mental welfare. It would encourage him in doing those things which it thinks he ought to do and discourage him in those things which it is evident he ought not to do. Hygiene would lend an attentive ear to the child's researches in the realm of ideas

and would answer his questions concerning the fundamental facts of existence with seriousness and as much wisdom as it can muster.

Finally, the child steps over the threshold of the school and enters on the last and longest lap of his journey. In school he mixes more generally with his kind and finds larger possibilities for experience with microbes which he may have missed elsewhere. Hygiene would reduce these experiences to a minimum by belated vaccinations, and by cultivating the sympathy and wits of teachers and parents so that the danger of infection is reduced to a minimum and the care of the infected raised to a maximum.

Again, hygiene goes hunting periodically into the physical and mental make-up of the child, finding and treating conditions, most of which should have been found and treated or prevented long before, had hygiene been as wise a few years ago as she now is. We can expect the need for medical and dental care of the school child to diminish only with better hygiene for the preschool child, the infant, the child in process of birth, and the unborn. The need will certainly not become less until this is the case.

School hygiene seeks to establish healthful physical and mental practices which likewise should have been formed at an earlier time.

Hygiene hopes for an understanding on the part of teachers and parents of the mental capacities and needs of every child so that his school tasks will be a stimulus rather than a source of depression to body and spirit. Finally along with a thirst for other knowledge, hygiene hopes to arouse, in at least a considerable proportion of pupils, an interest in hygiene which may help them to make the most of their own lives and to make healthier and happier the lives of children which are to be.

In all its ambitions for the child, hygiene is dependent on the help of workers in every other field of public health and medicine. It receives this assistance in ample measure. Even cold and impersonal vital statistics offers at least encouragement, for its figures afford every evidence that hygiene has, in the brief period of its existence, made the life of the child far less precarious and woeful than it was in past ages. The star of hygiene shines with increasing luster on the pathway of every child from his early prenatal to his last school days. Its influence is checked by conditions of the hour which make for poverty and neglect, the chief enemies of child welfare, but hygiene hopes that out of present economic ills will come a better order of society in which the health of all children will be of first concern.

# A Ten-Year Study of Toxin-Antitoxin Mixture and the Schick Test in the Control of Institutional Diphtheria

C. C. YOUNG, D.P.H., F.A.P.H.A., AND G. D. CUMMINGS

*Michigan Department of Health, Lansing, Mich.*

THE first attempt on the part of the Michigan Department of Health to demonstrate practically the value of toxin-antitoxin mixture and the Schick test was started in October, 1920. It was felt that a study carried out on a relatively stationary, well controlled group of individuals over a period of years would be quite significant. The population of the Michigan Home and Training School at Lapeer was selected as a satisfactory test group.

The diphtheria situation in this institution in 1920 made the conditions for a study of the effectiveness of toxin-antitoxin mixture almost ideal. Diphtheria had been endemic in the institution since its establishment in 1895. In 1920, as in all previous years, the continued presence of diphtheria was a serious economic problem.

Sixteen hundred and fifty-two inmates were first Schick tested with 0.2 c.c. intradermal injections of 1/50 m.l.d. diphtheria toxin diluted in saline. All tests were controlled with 0.2 c.c. injections of heat-killed toxin. Readings were made at 2- and 5-day intervals. Throat swabs were taken on all inmates at the time readings were made and tests made to discover carriers of virulent diphtheria bacilli, who numbered 33, or 1.9 per cent of the population, concentrated in 11 of 17 cottages.

The survey revealed 251 Schick positive reactions, or 15.1 per cent of the population. All positive reactors were given 3 doses of 3 L+ toxin-antitoxin mixture. A retest of the positives in July, 1921 (27 were absent), revealed that the number had been reduced from 224 to 24. They were given a second course of treatment with toxin-antitoxin mixture.

All admissions to the institution after 1920 were either Schick tested and immunized when indicated, or were given 3 doses of toxin-antitoxin mixture with no preliminary test. About 1925, 0.1 L+ toxin-antitoxin mixture was substituted for the 3 L+ mixture formerly employed.

The 1928 population was Schick tested by the institution staff and the positive reactors numbered 344 or 12.3 per cent in a population of 2,784. No testing was done to check the efficiency of the immunizing treatment. The institution remained free of diphtheria from the time of first immunization in 1920 until 1929, when a few cases appeared. This freedom from the disease presented a striking improvement over conditions prior to 1920.

The 1931 population was Schick tested by members of the department, and 441 positive reactors, or 17.5 per cent, were found in a population of 2,513.

TABLE I

SCHICK REACTORS IN POPULATION RESIDENT IN INSTITUTION IN 1920, 1928, 1931

<i>Year</i>	<i>Population</i>	<i>Pos. Reactors</i>	<i>Neg. Reactors</i>	<i>Per Cent Pos. Reactors</i>
1920	1,652	251 *	1,401	15.1
1928	2,784	344	2,440	12.3
1931 †	2,513	441	2,072	17.5
1931 **	2,929	679	2,250	30.1

\* This number reduced to 24 by additional immunization by July, 1921.

† Excluding 1931 admissions.

\*\* Including 1931 admissions up to July 16, 1931.

The 1931 population included 1,006 who were inmates in 1920. This group was Schick tested in the 1920, 1928, and 1931 surveys, and was continuously resident for 11 years. The results on this group have been singled out for presentation in this paper (Table II).

TABLE II

SCHICK REACTIONS IN 1,006 INMATES RESIDENT IN INSTITUTION FROM 1920 TO 1931

<i>Year</i>	<i>Total</i>	<i>No. Positives</i>	<i>No. Negatives</i>	<i>Per Cent Positives</i>
1920	1,006	151	855	15.0
1921 *	1,006	11	995	1.0
1928 †	1,006	104	902	10.3
1931	1,006	154	852	15.3

\* Retest after immunization of positives, second course of injections given.

† Another course of injections given, but no retest.

It will be recalled that of the total 1920 population 15.1 per cent were positive (251 in 1,652). Of the 1,006 members of the 1920 population 15.0 per cent were positive, which is probably fairly representative of the entire 1920 population.

The significant fact is that 1,006 members of the 1920 population should be reduced to 1.0 per cent positive in 1921, by artificial immunization, then revert to 10.3 per cent positive in 1928 and 15.3 per cent in 1931, despite treatment of all of the 1928 positives.

The course of reactions when studied in detail over the 11-year period through 3 Schick surveys, clarifies the situation (Table III).

TABLE III

COURSE OF REACTIONS OF 151 INMATES SCHICK POSITIVE IN 1920 AND RESIDENT IN INSTITUTION UNTIL 1931

1920 Schick Survey	1921 Re-Schick after immunization of all positives		1928 Schick Survey All positives given 3 doses 0.1 L TAT		1931 Schick Survey	
Pos.	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.
82		82		82		82
32		32		32	32	
15		15	15 †			15
11		11	11 †		11	
2	2 *			2		2
3	3 *			3	3	
1	1 *		1 †			1
5	5 *		5 †		5	
151	11	140	32	119	51	100
151	151		151		151	

\* These positives given another course of injections (3L+) with no subsequent Schick test until 1928.

† These positive given another course of injection (0.1L+) with no subsequent Schick test until 1931.

Eighty-two, or 58.5 per cent, of the above 1920 positives negative in 1921 following immunization were still negative by 1931. Twenty-six, or 18.5 per cent, of the 140 1920 positives immunized and negative in 1921 had again become positive by 1928, and an additional 32, or 22.7 per cent, had become positive by 1931. Of the 140 negatives in 1921 58, or 41.4 per cent, returned to positive. This indicates that toxin-antitoxin mixture as an immunizing agent has been 58.6 per cent efficient over a 10-year span, or 81.5 per cent over 7 years, as measured by the Schick test. The number of 1921 negatives turned positive by 1928 (26) was only 6 less than the number turned positive between 1928 and 1931. The rate of change from artificially immunized negatives to positives was greatly accelerated for the 3-year period 1928-1931 as compared with the period 1921-1928. Beyond the 7-year period a decline in the level of immunity would therefore be expected.

Five inmates required 2 separate courses of treatment to produce the Schick negative state, 3 of whom had again become positive by 1931. Six inmates required 3 courses of treatment, only 1 of whom was negative in the 1931 survey. Altogether, the 1931 survey revealed 51 positives, or 33.7 per cent of the 151 positive in 1920. This latter figure should not be accepted as an indication of immunizing efficiency as it included 5 inmates positive in 1921, 1 positive in 1921 and 1928, and 5 positive in 1921, 1928, and 1931.

Seven hundred and one, or 81.9 per cent of the 1920 negatives, remained negative over the 11-year period; 72, or 8.4 per cent of

TABLE IV

COURSE OF REACTIONS OF 855 INMATES NEGATIVE TO SCHICK TEST IN 1920 AND CONTINUOUSLY RESIDENT IN THE INSTITUTION UNTIL 1931

the 1920 negatives, became positive by 1928; and an additional 82, or 9.5 per cent, by 1931—a total of 154, or 17.9 per cent. Fifty-one of the 72 positives in 1928 were negative in 1931 due to immunization, while 21 were still positive. The total number of positives by 1931 was 103, or 12.0 per cent.

Of the 1,006 inmates, 151, or 15.0 per cent, were positive to the Schick test in 1920. This group was reduced to 11 by 1921 due to immunization. Ten years later, following a Schick survey and a re-immunization of positives in 1928, there were 154 positives, or 15.3 per cent. The total of 154 positives was comprised of 51 (5.0 per cent of 1,006 inmates) of original 1920 positives immunized once, twice, or three times, and 103 (10.3 per cent of 1,006 inmates) of original 1920 negatives who had become positive by 1931.

## DISCUSSION

The first information of significance in the foregoing figures is the unusually low number of Schick positive reactors in the previously unimmunized 1920 population. This percentage was practically identical for the whole 1920 population and for the portion which remained in the institution until 1931. Schick surveys on free living groups of all ages have been uniformly higher in percentage positiveness to the Schick test (Zingher,<sup>1</sup> Ceconi,<sup>2</sup> O'Brien *et al.*,<sup>3</sup> Griswold,<sup>4</sup> Crooks,<sup>5</sup> Cruickshank<sup>6</sup>).

On the other hand, Zingher<sup>1</sup> has reported institutional survey figures of 7.0 per cent Schick positives among males and 10.0 per cent in females. The total figure exceeds the percentage positiveness of the 1920 population reported here by 2.0 per cent.

This low percentage coupled with the continuous presence of diphtheria in the institution prior to 1920 points to a definite causal relationship.

Many Schick survey reports have indicated that, in general, city groups of low economic level existing under crowded conditions, have shown a higher grade of immunity than other city groups living in better circumstances (Park,<sup>7</sup> Zingher,<sup>1</sup> McClelland<sup>8</sup>). Dudley<sup>9, 10</sup> has reported that exposure to diphtheria will result in a high grade of immunity.

In view of the fact that admissions to the Michigan Home and Training School after 1920 averaged from 40 to 60 per cent positive to the Schick test, it would appear that the high grade of immunity found in the 1920 population of this institution was due to continuous exposure to true or sub-clinical diphtheria.

A second point of interest is the fact that 1,006 inmates were 15.0 per cent positive to the 1920 Schick test and 15.3 per cent positive 11 years later, despite the fact that the 15 per cent positives in 1920 were reduced to 1 per cent by 1921 through immunization. The 1931 positive reactors were made up of earlier natural and artificial immunes. The number of 1920 positives shown to be immune in 1921 following treatment who returned to the positive state by 1928, and the increased rate of return between 1928 and 1931, points to a period of artificially conferred immunity approximating 7 years. The fact that diphtheria reappeared in the institution in 1929 strongly supports this assumption.

The literature contains several references to the fluctuations of the Schick negative state. It has been shown by Parrish and Okell<sup>11</sup> that natural and artificial immunes may become positive to the Schick test over periods covering from 1 to 7 years. Park<sup>12</sup> has indicated in a study of artificial immunes, over a 5-year period that, although most cases remained negative, some doubtful positive readings were recovered. Dudley<sup>9, 10</sup> has indicated that exposure to diphtherial antigen may develop an immunity. O'Brien<sup>13</sup> has demonstrated in 6 positive cases that the Schick test may act as a secondary stimulus in the production of the Schick negative state. Our findings coupled with the above would seem to indicate that there are many individuals who tend to be borderline reactors, sometime positive, sometime negative, according to the type of influence. The removal of true or subclinical diphtheria as a factor tending to maintain immunity might, therefore, be instrumental in the gradual change from the natural immune to the positive state. This condition would represent the converse of Dudley's hypothesis.

At any rate, it is apparent that we must not only consider the change of reaction of artificial immunes and length of period of artificially conferred immunity, but also the fluctuations of the Schick negative state in so-called natural immunes.

Whether, under the double influence of artificial immunization and the elimination of true or subclinical diphtheria with its action upon borderline reactors, the percentage positiveness of a closed institutional group of this type tends toward a constant figure at any given time, remains to be determined in future studies. In this study, the constancy of the 15 per cent positive figure in 1920 and in 1931 on the same group was striking.

No commentary on the general efficiency of toxin-antitoxin mixture need be made despite the return of many reactors to the positive state. The general condition of the institution after 1920 as compared with the period before speaks for itself.

### SUMMARY

Schick survey results for 1920 have been presented on an institutional group resident over periods ranging from 1895 to 1920, on 1,006 members of the 1920 population resident for 11 years thereafter, and on the population of the institution in 1928 and 1931. It has been shown that the 1920 population was 15.1 per cent positive and that 1,006 patients of this same population resident during the 11 years thereafter were 15.0 per cent positive in 1920, 1.0 per cent positive in 1921 after treatment with toxin-antitoxin mixture and 15.3 per cent positive in 1931. It has also been shown that true or subclinical diphtheria was present as an influence on immunity before 1920 and absent thereafter. Schick results have been presented on 1,006 patients resident at the time of the 1920 survey and during 11 years thereafter indicating that the span of artificially produced immunity runs close to 7 years and that both artificially produced negatives and natural negatives tend to become positive over a given period.

### CONCLUSIONS

1. True or subclinical diphtheria may be a factor in maintaining a high degree of institutional immunity to the disease.
2. The span of artificially produced immunity as measured by the Schick test approximates 7 years, immunized positives returning rapidly to the positive state in the following years.
3. Natural or Schick negative reactors tend to return to the positive state with the elimination of the influence of true or subclinical diphtheria.
4. Administration procedure should include Schick surveys on immunized groups coinciding with the decline in the general level of immunity.
5. Schick surveys at intervals beyond the one over which the protection against diphtheria may be assumed should include original natural negative reactors as well as artificially immunized negative reactors.

# The Infection of Cows with *B. abortus* Variety of *Brucella* from a Public Health Standpoint

HARRIET LESLIE WILCOX

*Bureau of Laboratories of the Department of Health  
of the City of New York, N. Y.*

NUMEROUS articles have appeared during the last few years on the occurrence of undulant fever in man. The majority of the cases reported have been in the agricultural or cattle raising centers of the middle West and have been traced to the consumption of milk from cows infected with *Brucella* organism or to the handling of infected carcasses.

Investigations, stimulated by these reports, have shown that the infection of cattle is not limited to any one section but is endemic throughout the United States. This has led to further agitation by public health officers to have all milk supplies pasteurized.

The following study was begun in 1930, at which time the Research Laboratory commenced the routine diagnosis of cow serums for *Brucella* infection.

The scope of the work was (1) the examination of the herd, which furnished milk to the tuberculous patients at the Municipal Sanatorium at Otisville, N. Y., for *B. abortus* infection by the agglutination test; (2) the isolation of the organism from the milk of the positive reacting cows and the determination of the variety of *Brucella* found, and (3) the titration of the patients' serums for agglutinins specific for this type.

The serums of 103 cows were examined. Twenty-seven, or 26.2 per cent, showed complete or strong agglutination in a dilution of 1:50.

The milk of 21 of the positive reactors was examined for agglutinins and the *Brucella* organism. Seventeen cows were found to have specific agglutinins, and *Brucella* was isolated from the milk of 13. Data on these cows are given in Table I.

Three cows, C89, C60, and D5, gave histories of having aborted, 1 in 1929 and 2 in 1930. Two, C89 and C60, calved normally subsequently. The third, D5, was with calf when sold in 1931. Cow C31

TABLE I

calved in 1929 but remained sterile in 1930, and C93 was sterile in 1931 though her calving had been normal in 1929 and 1930.

Agglutinin absorption tests showed that the strains belonged to the same serological group. A rabbit was immunized with strain B92, and reciprocal agglutination tests were made with its serum and specific serum for strain 426 \* which Evans<sup>1</sup> classified as belonging to *B. abortus* variety.

The 11 other strains were found to absorb to the same degree the agglutinins from serum 426 as strain B92.

The ability of these strains to absorb the agglutinins in the melitensis serum for its specific strain 428 and for themselves was then

\* This culture was obtained from the National Institute of Health, Washington, D. C.

ascertained. It was found that the cow strains reduced markedly or completely the agglutinins for themselves, whereas the agglutinins for strain 428 were removed only in the higher dilutions.

Theobald Smith and others have stated that it is not possible to differentiate the bovine from the swine strain by agglutinin absorption. Nevertheless the following absorption test was made:

A porcine strain DK obtained from Dr. K. F. Meyer was injected into rabbits to obtain specific serum for this variety. Absorption tests of agglutinins from serum DK and 426 corroborated the statement that *B. abortus suis* and *B. abortus bovine* cannot be differentiated by this method.

Huddleson<sup>2</sup> recommends the bacteriostatic effect of certain dyes to differentiate the *B. abortus* suis from *B. abortus* bovine. He has found that basic fuchsin and thionin in specified dilutions will inhibit respectively the porcine and bovine strains. The 13 bovine strains and swine strain DK were therefore plated on liver agar to which basic fuchsin and thionin were added so that the final dilutions of the dyes were 1-25,000 and 1-50,000. Duplicate control plates of liver agar were also inoculated, 1 of which was incubated in ordinary atmosphere and the other with the dye plates under CO<sub>2</sub>. The suspension of the organisms which was used for the inoculum was so standardized that discrete colonies were obtained. The thionin in both dilutions inhibited the growth of the cow strains, but permitted the development of strain DK. The basic fuchsin on the other hand inhibited the porcine strain but did not prevent the growth of the cow strains.

Since the isolation of *B. abortus* bovine by Bang<sup>3</sup> in 1927, numerous writers have emphasized the fact that this organism requires an atmosphere containing carbon dioxide for its isolation on artificial mediums. On the other hand, Smith<sup>4</sup> stated: "All reports on the isolation of the swine strains agree that carbon dioxide sealing is unnecessary from the start." In a later article<sup>5</sup> he said that sealing had a distinct retarding effect upon 3 of the swine strains he studied.

Comparative methods of cultivation under CO<sub>2</sub> and in the ordinary atmosphere were, unfortunately, not used for the isolation of the strains. However, the sensitivity of some of the cultures towards CO<sub>2</sub> was definitely indicated. For example the fishings made from the plates inoculated with milk from cows B92 and C61 were grown aerobically and in CO<sub>2</sub>. In CO<sub>2</sub> growth appeared earlier and was more abundant. Plates inoculated with milk from cow C89 were incubated with and without CO<sub>2</sub>. Growth was obtained only under CO<sub>2</sub>. Tissue cultures from guinea pigs injected with milk from 7 cows, C60, C93, C1, B92, C61, J4, and C89, yielded growth under CO<sub>2</sub>, while similar plantings in the ordinary atmosphere of the incubator remained sterile. An abundant growth was obtained from the spleen of a guinea pig inoculated with milk of cow D5 under CO<sub>2</sub> whereas the cultures grown aerobically showed only a few scattered colonies.

Additional evidence of the favorable effect of CO<sub>2</sub> upon certain strains is shown by the control plates of the dye test. Though 4 strains, C70, C71, C61, and D5, grew well in the ordinary atmosphere when cultured in high dilution, strain C61 had required CO<sub>2</sub> for its isolation from the guinea pig tissue and the growth of D5 had been markedly increased. Three strains, C31, J4, and B54, had produced

larger and more numerous colonies under  $\text{CO}_2$  and 6 strains, C93, C1, C89, B92, and C41, exhibited growth only under  $\text{CO}_2$ . Thus the growth of 11 strains was favorably influenced by  $\text{CO}_2$ .

McAlpine and Slanetz recommend the utilization of glucose as a means of differentiating the porcine and bovine strains. They found that the former used from 4 per cent to 18 per cent of the available sugar as against 2 per cent or less by the bovine cultures. Since the sugar is not fermented in appreciable amounts, these strains produced a larger amount of  $\text{NH}_3$  than the porcine cultures.

Following the procedure advised by these writers, 2 porcine and 8 bovine strains were examined for their utilization of sugar and production of  $\text{NH}_3$ .<sup>\*</sup> It was found that 1 of the porcine strains, 438, used the largest percentage of sugar, but, contrary to the results of McAlpine and Slanetz, it produced the largest amount of  $\text{NH}_3$ . The 8 bovine strains used from 4 per cent to 11 per cent of the available sugar, thus placing them in the porcine group if we accept this method of classification. Meyer and Zobell<sup>7</sup> have subjected 73 strains—33 abortus, 20 melitensis and 19 suis, to this test. They conclude "the quantitative determination failed to demonstrate any appreciable differences in the dextrose utilization."

Through the courtesy of Dr. Louis Cohen, Medical Superintendent at the Municipal Sanatorium, Otisville, N. Y., serum from 223 patients was obtained, representing approximately 65 per cent of the total number in the hospital from March 28 to June 4, 1930, the period in which the examinations were made. Personal objection or condition of the patient prevented the taking of the blood from the remainder.

Four patients were found to be positive reactors and 6 partial reactors. The titrations are shown in Table III.

The history of patient J. S. whose serum agglutinated completely in a dilution of 1-640 is as follows:

J. S., a case of bilateral moderately advanced tuberculosis, admitted November, 1927. No particular complaint until February 15, 1930, when he suffered severe headache, pains in abdomen and painful articulations. This patient, always apyretic before, had a continuous type of temperature ranging around  $101^\circ \text{F}$ . from February 20 to April 9, 1930. This condition left him as suddenly as it appeared. By May 19, 1930, he had apparently recovered but continued to feel weak and was losing weight. The lung condition was about stationary.

This was the only case of those showing agglutinins which manifested symptoms typical of *Brucella* infection. The stool and blood cultures made May 13 and May 22 respectively yielded no *Brucella*

<sup>\*</sup> The determinations were made by Miss McGuire of the Harriman Research Laboratory through the courtesy of its Director, Dr. Falk.

organisms. The feces were examined according to the procedure of Amoss and Poston.<sup>6</sup> The blood culture was examined weekly for a month. It is possible that a slight infection may have occurred in the other 3 positive reactors which was obscured by the tuberculous condition.

The presence of Brucella agglutinins in the blood serum of man with the absence of clinical signs of infection has been reported by various writers. The following experiment was undertaken to see if rabbits fed with milk containing a live avirulent strain of *B. abortus* as well as a heated suspension of the same organism would produce Brucella agglutinins.

Strain *B. abortus* 426 was used for the feeding. This culture was

grown on liver agar for 48 hours, and after suspension in NaCl was standardized by the Wright method. Half of every suspension was heated to 60°–65° C. for 1 hour, after which sterility tests were made. When the number of organisms had been ascertained, the dead and living suspensions were diluted to the desired number with sterile milk.

Mortality was high from extraneous causes in rabbits receiving both living and dead suspensions. All of the rabbits did not respond by the production of agglutinins. The time of the appearance of these antibodies varied, but as a rule 5 to 6 weeks' feeding was required before the maximum titers were obtained.

Fifteen rabbits were fed dead suspension in the first series. Eight of these died between the 9th and 19th day of feeding, 3 of which showed a slight response. Four rabbits, 101, 120, 425 and 296, though fed for a period of 7 weeks showed no agglutinins. Nedzel and Arnold<sup>7</sup> found that by suspending *B. prodigiosus* in egg white and injecting directly into the duodenum the absorption from the intestinal tract into the blood stream was markedly increased, and concluded that the egg white increased the permeability of the intestinal wall. Rabbits 425 and 296 were given 5 c.c. of egg white before feeding the infected milk for 5 days, but neither responded with agglutinin production. To determine whether these animals were refractory to the artificial stimulation of agglutinins they were given intravenous injections of dead *B. abortus*. The serum of 425 gave complete agglutination in a dilution of 1:1,600, while that of 296 gave a strong reaction in the same titer. Four rabbits, 442, 115, 940, and 315, responded to the feeding by agglutinin production.

Six rabbits were fed the live suspension. Two died the 11th and 16th day without the appearance of agglutinins. Rabbit 118 showed agglutinins on the 18th day of feeding but died 2 days later. Rabbit 258 was fed for 22 days, when feeding was discontinued as no agglutinins had appeared. Rabbit 219 showed a maximum titer on the 34th day when feeding was stopped. The serum of rabbit 609 showed its highest titer on the 30th day. Despite the continued feeding, the titer was not increased.

The serum titers of 3 rabbits in the second series were higher than those in the previous feeding experiment probably due to the larger doses given. Four rabbits were fed dead suspensions, approximately 200 billion daily. The serum of rabbit 501 showed a strong reaction in a dilution of 1:800 on the 17th day of feeding, but died the day following the last bleeding. Rabbits 503, 522, and 523 responded poorly to the feeding and despite the continued inoculations *per os* the titers of their serums decreased.

The serums of 3 rabbits fed the live suspensions exhibited agglutinins in relatively high dilutions. Rabbits 521, 636, and 287 gave strong reactions in dilutions of 1:800, 1:1,600, and 1:6,400 respectively. Under continued feeding the titers of rabbits 521 and 636 were maintained while the agglutinins of rabbit 287 showed a gradual decrease. Tables IV and V give the doses and appearance of agglutinins.

TABLE IV  
AGGLUTININS PRODUCED BY FEEDING *B. abortus*—EXPERIMENT 1

	Rabbit	No. of <i>B. abortus</i> in Billions	No. of Days Fed	Day on which Maximum Titer Was Reached	Dilution of Serums	Percentage of Agglutination
Killed <i>B. abortus</i>	115	*	31	28	1 - 200	100
	315	200	38	33	1 - 200	75
	442	200	14	13	1 - 100	100
	940	200	37	28	1 - 200	75
Living <i>B. abortus</i>	219	†	31	34	1 - 800	75
	609	200	49	30	1 - 800	100

\* Rabbit 115 received 20 million April 10-24  
50 billion May 1-4  
100 billion May 5-8

† Rabbit 219 received 20 million April 10-30  
50 billion May 1-4  
100 billion May 5-12

Since the ingestion of dead and live *Brucella* organisms may result in the production of agglutinins in experimental animals, it is not surprising to find these antibodies in the serums of a small percentage of the patients at the Otisville Sanatorium. Every patient was required to drink daily at least 3 pints of milk, which was raw and came from a herd of which 26 per cent was found to be infected with the *Brucella* organism. The milk of 17, or 80 per cent of the 21 cows whose milk was examined, showed agglutinins in the whey which indicated infection of the udder. That only 1 patient presented evidence of clinical infection emphasizes the low virulence of these strains for man.

TABLE V  
AGGLUTININS PRODUCED BY FEEDING *B. abortus*—EXPERIMENT 2

	Rabbit	No. of <i>B. abortus</i> in Billions	No. of Days Fed	Day on which Maximum Titer Was Reached	Dilutions of Serums	Percentage of Agglutination
Killed <i>B. abortus</i>	501	200	17	17	1 - 800	75
	503	200	52	11	1 - 50	75

	521	200	43	34	1 - 800	100
	287	200	58	33	1 - 6,400	75

## SUMMARY

The serums of 103 cows were examined for *Brucella* agglutinins. Twenty-seven, or 26.2 per cent, showed a complete or strong reaction in a dilution of 1:50 or higher.

The milk of 21 reactors was tested for the presence of agglutinins and *Brucella* organisms. The milk whey of 17 cows showed agglutinins. Of these 7 gave complete or strong reactions in a dilution of 1:200, 5 showed complete or strong reaction in a dilution of 1:50, and 5 showed partial reactions in dilution of 1:25 and 1:50 of the milk whey. The milk of 13 cows yielded *Brucella* organisms.

The 13 strains were found to belong to the bovine variety of *Brucella* by the bacteriostatic action of basic fuchsin and thionin.

Eight strains were tested for their ability to use glucose. All were found to utilize this sugar in amounts that would classify them as porcine strains. One swine strain used as control utilized the largest percentage of sugar and coincidentally produced the largest amount of  $\text{NH}_3$ .

The test for the reciprocal absorption of agglutinins from serums specific for porcine and bovine strains showed that this method could not be used to differentiate them.

The serums of 223 patients who drank milk from this herd were examined for *Brucella* agglutinins. Ten were found to have antibodies in their blood. One, whose serum showed a complete reaction in a dilution of 1:640, gave a history indicative of *Brucella* infection. Three whose serums showed a strong reaction

in a dilution of 1:100 manifested no clinical signs of infection. The serums of 6 showed partial reactions in dilutions of 1:100 or lower.

It has been shown in experimental animals that it is possible to stimulate the production of agglutinins by daily feedings of large numbers of dead and living *B. abortus*.

Abortion occurred in 3 of the 13 cows from which *Brucella* was isolated. Two of the 3 calved normally the following year and 1 gave birth to a sickly calf. Ten cows gave no history of abortion though found to be shedders of *B. abortus*. Two of these animals subsequently became sterile.

### CONCLUSIONS

The milk of cows infected with the bovine variety of *B. abortus* is a potential source of infection for man.

The danger of infection is relatively small when milk contaminated with the bovine variety is considerably diluted.

*Brucella* agglutinins may be present in the blood of man due to the consumption of milk containing *B. abortus*. These antibodies may occur in the absence of clinical symptoms.

Cows in whom abortions have occurred may develop immunity so that they calve normally and still continue to excrete *B. abortus* in their milk.

## Esthonia Day Nurseries

A RECENT law requires the owners of factories to establish day nurseries close to the factories. The day nurseries are to be open to children under 8 years of age all the year round during the hours of daily work; besides the children whose mothers are employed the day nurseries will also take care of children deprived of mothers but whose fathers or other persons caring for them are employed. Detailed regulations are prescribed for the conduct of these nurseries; a trained staff must be employed.—*Maternita ed Infanzia*, Rome, June 1932, p. 611.

## ALCOHOL AND INHERITANCE

THE work of Stockard, of Cornell University, in 1913 and 1914, on guinea pigs is well known. Based on a long series of experiments in which guinea pigs were kept alcoholized for different periods, Stockard concluded that the presence of alcohol in the circulation injured the germ plasm and produced permanent deterioration of the race, even though the subjects directly exposed were not injured. He found, however, that by the end of four generations the surviving guinea pigs were of superior quality and lived longer than any others previously known, due to elimination of the weaker and defectives.

This report of the Medical Research Council of England<sup>1</sup> gives details of experiments duplicating those of Stockard which have been carried out with greater care, especially in regard to the genetic qualities of the races used. There were matings between males and females both thoroughly alcoholized for periods of from 1 month to 5 years, and 4 successive generations were treated. Also, there were matings between alcoholized males with normal females, and normal males with alcoholized females. There was only one abnormality among 674 control animals, against 10 among 6,309 of those alcoholized.

The general conclusion was that alcohol has no deleterious effect

on the genetic behavior of guinea pigs. Fertility appeared to be unaffected. Males are no more affected than females. Some evidence indicated that there was a deterioration in weight in the descendants of alcoholized stock. The mortality rate for stillbirths and deaths during the first 3 weeks of life is greater for the offspring of directly alcoholized than of the untreated animals, but the highest mortality among such offspring occurred when the parents had been treated over a period of approximately 2 years. The authors believe that this increased mortality might be accounted for by the age of the parents.

In explaining the difference between their results and those of Stockard, it is suggested that the latter had not adequately controlled the genetic behavior of his stock, and that the results which he attributed to alcohol came about through the introduction of one or more parents with unobserved but inheritable qualities able to bring about the effects seen. It is further suggested that his results may have been influenced by some undetected defect in the diets given his animals; in other words, that the effects were due to alcohol plus a deficiency of vitamins. The experiments now reported do not indicate that alcohol *per se* is capable of producing a transmissible injury to the germ cells.

The experiments were carried out with the utmost care over a period of years, and errors do not appear to have crept in. By the same token, there are few more careful workers than Stockard, and until some explanation is brought forward, it seems impossible to reconcile the directly opposite results obtained by him and by the workers of the Medical Research Council. We must remember also that results similar to those of Stockard have been obtained by Pearl of Johns Hopkins in birds, and by other observers in lower forms of life. The authors of the present report, however, state that their results seem to agree with those of the majority of observers in this field.

The report concludes with a statement that these results should not be used by either prohibitionists or those who advocate the use of alcohol by human beings. The study was a purely scientific one, and the authors decry any application to social affairs. It is unlikely that further experiments along this line will be carried out by them on account of the time and labor required. In this country, with the very strong probability that there will be some modification, if not entire abolition, of our prohibition laws, it will be impossible to keep people from making this application of scientific results. Whether or not they are so applied, scientific people are interested

only in the truth. The report must be considered as a valuable contribution to our knowledge of the subject, though we feel reasonably sure that the conclusions will be attacked in one way or the other.

## NEW OCCASIONS — NEW DUTIES

LOWELL once said, "New occasions teach new duties: time makes ancient good uncouth." There is a lesson in public health in the utterance.

This is a new occasion. The world is in the throes of a depression made deeper by the heights to which the world rose before. Layman and professional man alike have taken inventory of the changes the new occasion has made about them. They are many and unusual.

Time makes ancient good uncouth. We have advanced with time and the standards of sewage disposal of an ancient day are today unfit. We have built up treatment works that are examples of the engineer's ability to adapt the principles of science to the difficult task of sanitation. The chemical, biological and mechanical devices have stood as bulwarks between the contaminating flow of municipal waste water and the streams which must be kept clean.

As a result, water supplies have functioned under reduced bacterial loads, despite the continued concentration of population in cities. Fish life has returned to haunts long devoid of aquatic life. Bathing and shell fish areas have again become safe for man's external and internal person. The esthetic sense of the nation is no longer shocked by the sight of floating fecal matter and gassing sludge banks.

Comes the new occasion. The depression has caused municipalities to cast frantically about in search of those services which can stand deep appropriation cuts without producing loud protests from the tax payers. Sewage treatment has, somehow, filled these specifications ideally. Out-of-the-way location, lack of information on the part of the citizens—and the officials themselves—have tempted municipalities to reduce operating funds for sewage treatment. Too many sewage treatment works have been crippled by reductions in personnel and appropriations to permit us to disregard the tendency of other economy seekers to follow suit.

There is danger in such a procedure, a danger that strikes the whole public health field because of the close relation between sewage treatment and mass hygiene. The production of a satisfactory

effluent becomes difficult, streams again become contaminated and unsightly, and the lack of proper and intelligent attention results in a costly deterioration of the costly installations.

We cannot forget that the ancient good is uncouth today. We cannot allow a hard earned public health victory to slip away from us. The new occasion, the depression, teaches us new duties. It is for every health worker to understand and make others understand the vital rôle that sewage treatment plays in the nation's health.

*It will be greatly appreciated if members and subscribers will promptly notify the office of the Association of any change of address.*

# ASSOCIATION NEWS

## SOUTHERN BRANCH A.P.H.A.

THE strength of any organization depends largely upon the strength of its constituent elements. Recognizing this fact and recognizing the far reaching interest of any association of public health workers in America, the southern states are developing a Southern Branch of the American Public Health Association under authority conferred by action of the Executive Board. The development has a two-fold objective:

First—The strengthening of southern membership in the American Public Health Association as the representative professional association of public health workers in America.

Second—The exchange of experience and information relative to public health problems more or less peculiar to the South and sub-tropical regions.

Obviously there will be special problems of peculiar interest to the South, and just as obviously a much larger body of workers can be assembled for regional meetings than could be assembled at remote national meetings. An additional advantage, however, is that attendance at national meetings will be stimulated because of increased interest in the Association as a whole,

membership in the parent association being an absolute requirement for membership in the Southern Branch.

The movement was started under very favorable auspices by Dr. Louis I. Dublin, President, at the Tennessee Conference of Public Health Workers last winter. Since that time Tennessee membership in the parent association has been increased from 68 to 162, and at present state health officers in most of the southern states are engaged in stimulating membership for their states.

The first meeting is to be held in Birmingham, Ala., November 14-16, just preceding and conjointly with the Southern Medical Association which itself has a section on public health. In addition, during the same week the National Malaria Committee is meeting, and hence opportunity is afforded to attend three public health programs in the space of one week. The secretaries of these several organizations are working together for development of a program of universal interest with no overlapping. A most successful meeting seems to be in prospect and it is to be hoped that the Southern Branch will be an unqualified success as has been the Western Branch.

## NEW MEMBERS

*The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.*

### *Health Officers Section*

Squire R. Boggess, M.D., Lawrenceburg, Ky.,  
Health Officer

G. S. Brock, M.D., London, Ky., Director,  
Laurel County Health Department

D. G. Caldwell, M.D., Concord, N. C.,  
Cabarrus County Health Officer

George Y. Davis, M.D., 4329 Euclid Blvd.,  
Youngstown, O., County Health Commissioner

Malcolm T. Foster, M.D., Mt. Airy, N. C.,  
Surry County Health Officer

Ollie M. Goodloe, M.D., Federal Bldg., Jackson, Ky., Director, Breathitt County Health Department

Minerva Gordon, M.D., 324 Pennington Ave.,  
Trenton, N. J., licensed Health Officer in  
New Jersey

F. G. Granger, M.D., Dothan, Ala., County  
Health Officer

Arthur M. Johnson, M.D., Health Bureau,  
Rochester, N. Y., Health Officer

Norris C. Knight, M.D., Indianola, Miss.,  
Director, Sunflower County Health Depart-  
ment

Dr. Edward L. McIntosh, Camden, Ala.,  
County Health Officer

Theodore Meyer, M.D., 28 High St., New  
Haven, Conn., Student

Ransley J. Miller, M.D., 909 Kansas Ave.,  
Topeka, Kans., City Health Officer

Charles R. Morton, M.D., Madisonville, Ky.,  
County Health Officer, Hopkins County

Percy L. Querens, M.D., 2703 Napoleon Ave.,  
New Orleans, La., Associate Professor of  
Preventive Medicine, Tulane Post-Graduate  
School of Medicine; Assistant Health Officer

E. T. Riley, M.D., Frenchburg, Ky., Health  
Officer

Louis P. Schubert, 58 S. Main St., Manville,  
N. J., Health Officer

James P. Sharon, M.D., 516 First State Bank  
Bldg., Fort Dodge, Ia., City Physician

Hilton J. Shelley, M.D., 35 South St., Middle-  
town, N. Y., Health Officer

Dr. Charles S. Stern, 7525 W. Greenfield Ave.,  
West Allis, Wis., Commissioner of Health

C. C. Threlkel, M.D., Morgantown, Ky.,  
Director, Butler County Health Department

W. H. Wheeler, M.D., West Liberty, Ky.,  
Director, Morgan County Health Depart-  
ment

#### *Laboratory Section*

LaVerne A. Barnes, Ph.D., 375 South St.,  
Jamaica Plain, Mass., Senior Bacteriologist,  
State Department of Health

Jean Broadhurst, Teachers College, Columbia  
University, New York, N. Y., Professor of  
Bacteriology

Maurice Brodie, M.D., Department of Bac-  
teriology, McGill University, Montreal, Que.,  
Research Worker

George A. Denison, M.D., Box 2591, Board of  
Health, Birmingham, Ala., Director, Bureau  
of Laboratories

William A. Hagan, D.V.M., 320 The Parkway,  
Ithaca, N. Y., Professor of Veterinary  
Bacteriology, Cornell University

N. Paul Hudson, M.D., Ph.D., University of  
Chicago, Chicago, Ill., Professor of Bac-  
teriology

George A. Knaysi, Ph.D., Ithaca, N. Y.,  
Assistant Professor of Bacteriology, Cornell  
University

Benjamin S. Levine, Ph.D., 159 North Dear-  
born St., Chicago, Ill., Director, Clinical  
Laboratory, Public Health Institute

Wade W. Oliver, M.D., 335 Henry St., Brook-  
lyn, N. Y., Professor of Bacteriology and

Immunology, Long Island College of  
Medicine

#### *Vital Statistics Section*

William K. Kirk, 627 Franklin Ave., Steuben-  
ville, O., Manufacturer of Therapeutic  
Appliances (Assoc.)

#### *Public Health Engineering Section*

Daniel J. Adams, Port Norris, N. J., Sanitary  
Inspector

Stanton L. Dorsey, B.S., 791 Arlington Bldg.,  
Washington, D. C., Sanitary Engineer,  
U.S.V.A.

James S. Allen, D.V.M., P. O. 203, Idaho Falls,  
Ida., Milk and Sanitary Inspector

Thomas M. Dugan, 1308 Freemont St.,  
McKeesport, Pa., President, American  
Society of Sanitary Engineers

Walter A. Helbig, B.S. in C.E., Darco Sales  
Corporation, 45 E. 42 St., New York, N. Y.,  
Sanitary Engineer

Paul Molitor, Sr., 4 Willow St., Chatham,  
N. J., Consulting Operating Engineer

Control, U. S. Public Health Service

## LETTER FROM GREAT BRITAIN

THE STATE OF THE PUBLIC  
HEALTH IN ENGLAND

FROM the returns published in the annual report of Sir George Newman, the Chief Medical Officer of the Ministry of Health, for 1931, it does not appear that the financial crisis and the trade depression have had any very marked effect upon mortality and morbidity rates in England and Wales. The death rate for the year and the infantile mortality rate, it is true, are slightly higher than in the preceding year (12.3 and 66 as against 11.4 and 60), but these variations cannot be regarded as anything out of the way.

Commenting upon the causes of death, Sir George points out that death by injury on roads, etc., today stands among the first seven or eight principal causes of mortality. The death rate of 16 per 100,000 is practically double what it was in 1921.

So far as communicable disease was concerned, 1931 appears to have been not unfavorable. Smallpox (*variola minor*) which had been providing 10,000 to 14,000 cases a year from 1926, gave only 5,664. There was a welcome fall

also in the number of cases of and deaths from the majority of diseases in the group, notably diphtheria, scarlet fever, and tuberculosis. Infectious diseases of the nervous system (poliomyelitis, encephalitis, etc.) were also less prevalent. The number of cases of the former—339 with 63 deaths—was the lowest since 1922.

The fact that the maternal mortality rate continues stubbornly in the neighborhood of 4 per 1,000 live births is noted. Though progress has been made in relation to maternity as well as child welfare work, it is mentioned that economic difficulties have prevented some of the expansion and development that it had been hoped might take place following the work and reports of the Maternal Mortality Committee.

In relation to schemes affecting tuberculosis, venereal disease, and cancer, the reports offer reasons for belief that there has been progress also. Greater use has been made of the facilities provided for diagnosis and treatment in the case of the first two particularly, and reference is made to a number of interesting and practical investigations into the treat-

ment of tuberculosis and the causation of cancer.

#### THE "SEMBLANCE OF INCREASE" IN HEART DISEASE MORTALITY

IN the section dealing with cancer a careful and convincing analysis is made of the cancer statistics with the object of backing up a warning against too readily accepting the growing figures for the crude mortality rate from cancer as evidence of a marked increase in the fatality of the disease.

Rheumatic diseases, to which growing attention has been given during the last few years, have a section entirely to themselves. Acute rheumatism, it is noted, affords "one of the major opportunities of preventive medicine, the fleeting opportunity to prevent organic heart disease." This opportunity some of the great cities have seized while others hang back. The mortality ascribed to rheumatic fever continued to fall, the rate now being less than half that of 1901.

As regards heart disease, the statement of the Registrar-General made in 1928 is repeated that the "semblance of increase" in heart disease mortality is largely fictitious, being due to the increasing age of the population and the change in the practice of death certification which makes much more frequent record of degenerative changes in the heart muscle than was customary a few years ago. In the younger age groups in which rheumatism is a main factor, mortality from heart disease shows a considerable reduction.

#### A HEALTH EDUCATION CONFERENCE

THE Society of Medical Officers of Health appears to be one of the few bodies in this country that does not arrange for an annual conference on its own account. To some extent, no doubt, this is due to the fact that other bodies, notably the Royal Sanitary Institute and

the British Medical Association, at their annual meetings provide facilities for medical officers to confer or for discussions on subjects in which they are interested. The nearest that the society gets to arranging meetings of the type of the annual conference is in connection with a body known as the Central Council for Health Education, which owes its existence to the society and, containing a large representation from it, lives and moves and has a great part of its being in the house of the society.

The objects of the Council, which to a very large extent it secures, are to bring together the various voluntary organizations engaged in health education and to make contact between the organizations and authorities and others who may require their services. The annual conference is held partly in order to advertise the Council, and partly to give the bodies brought together as a result an opportunity of getting together. Recognition is in general given by the Ministry of Health, and health authorities and organizations in sizeable numbers accept the invitation to attend the meeting.

The conference this year is the fifth of the series and is to be held at the London School of Hygiene and Tropical Medicine on November 17. The Minister of Health (Sir E. Hilton Young) has promised to preside and will deliver an address. At the morning session the subject for discussion is "The Churches and the People's Health," to be opened by two representative clergymen of whom the Very Reverend W. R. Inge ("The Gloomy Dean") will be one. In the afternoon, representatives of voluntary health organizations and others will put up a discussion on "The Positive in Health Education." As the phrases "A positive health policy" and "The need for positive health teaching" have been bandied about a good deal of late in certain health propaganda society circles, the opportunity of

talking on this subject will receive wide and ready acceptance.

#### THE INSURANCE MEDICAL SERVICE

DISCUSSING the work of the insurance medical service, Sir George Newman puts the cost of medical benefit, exclusive of the cost of administration, at £9,497,616, of which over 7 millions sterling was expended in the remuneration of medical practitioners, and about 2½ millions in the supply of medicines and appliances. The amount of time lost by insured persons on account of sickness amounted to 26½ million weeks (509,615 years) or an equivalent of 12 months' work of about 510,000 persons.

The fact of the steady increase in claims for benefit and the causes thereof are discussed at some length. With a view to insuring exercise of greater care in connection with the issue of certificates by insurance physicians, a staff of regional medical officers has been appointed. Though it has only been at work a comparatively short time this staff has already succeeded in securing great improvements in the standard of certification in a number of areas.

In spite of difficulties such as these, that there has been real benefit to the workers as a result of the operation of national health insurance Sir George Newman has no difficulty in showing. More important still, he finds himself able to prove that as a result of the efforts of the practitioners undertaking insurance work—approximately 70 per cent of the registered medical practitioners in England and Wales—much progress in the direction of prevention has been and is being made.

The total number of insured persons is about 16 millions and for these provision is made under the system for securing the two essentials of all preventive medicine—the early clinical

diagnosis of sickness and the ascertainment of its causation.

#### THE COST OF PUBLIC HEALTH WORK

APART from his examination of the cost of the insurance service, Sir George Newman submits figures showing the cost of public health work generally in England and Wales and discusses as to whether or not the expenditure is justified and whether or not the justification is sufficient to warrant its continuance.

The annual expenditure on all public health works totals £57,370,000 (about 200 million dollars). This covers everything, including housing, water supply, sewage and refuse disposal, etc., but excludes voluntary funds and resources, expenditure on institutions for the insane, etc. In the list of what is secured for the money there are probably several items that the determined economist would mark as unnecessary. If he will study the report, however, and recognize what the information given means and, particularly, if he will compare what is spent on health with what goes in other ways, on education for example, or amusements, or alcohol, or tobacco, he must conclude that the money is well spent. He will understand also just why the Government, acting on the advice of the Minister of Health that it was not economy, it was waste, to fail to maintain the nation's health, has determined that the essential health services shall be continued unimpaired.

Sir George Newman's "State of the Public Health" for 1931 is an attractive and inspiring volume, and though, naturally, it will interest most intimately health workers here, as always, its appeal will be international and to workers in the field of preventive medicine generally.

CHARLES PORTER, M.D.

London

# PUBLIC HEALTH ADMINISTRATION

**Smallpox Types**—The mild form of smallpox commonly designated by its Portuguese name, *alastrim*, has prevailed over vast regions of the United States for over 30 years. It is estimated that the germ of this disease must have been transmitted from one human being to another more than 800 times and yet it is bred true. Throughout all these "generations" the organism maintains its early characteristics.

Cases of this mild strain of smallpox, like those of most contagious diseases, exhibit many minor variations, but without the development of a permanent new type. These variations are of the fluctuating type. No evidence has been found that the mild strain has ever reverted to the classical type, that is, that the pathogen of the disease has ever undergone a mutation in that direction. While it is true that there have occurred in the United States many outbreaks of severe classical smallpox, the cases have been most numerous near the Mexican border and at seaports. A large number of these outbreaks of the severer strain have been definitely shown to have arisen from outside the borders of the United States. Most American health officers and epidemiologists who have had experience with the two types of smallpox do not believe that as yet there has been any reversion of the mild strain to the old classical strain.—Charles V. Chapin and Joseph Smith, *Permanency of the Mild Type of Smallpox*, *J. Prev. Med.*, 6:273 (July), 1932.

**Poliomyelitis in New York**—During the epidemic which occurred in upstate New York in 1931 there were 2,020 cases of poliomyelitis. While the peak of the epidemic for New York City occurred in the first week of August, in

the remainder of the state the high point was not reached until the first and third weeks of September. Of all the upstate cases 77 per cent occurred in 16 counties which lie along the Hudson River valley and in that part of Long Island outside of New York City. These counties contain only 36 per cent of the upstate population. The three counties immediately adjacent to New York City, Nassau, Suffolk, and Westchester were responsible for 43 per cent of the entire number in the outbreak.

Of the total cases reported 57 per cent were diagnosed and reported before the occurrence of paralysis. In the 1916 epidemic there were 901 deaths among 4,215 reported cases, a fatality rate of 21.4 per cent. In the year 1931 there were reported 2,051 cases with 164 deaths, a fatality rate of 8 per cent.

The author suggests that any one of several factors or a combination of such factors may have been responsible for the decrease in the fatality rate: (1) The virus may have been less virulent. (2) The earlier diagnosis and better general medical and nursing care and the large use of hospital treatment may have been responsible. (3) The use of serum may have produced the more favorable result.

More than 140,000 c.c. of serum was collected from persons who had previously suffered from poliomyelitis and was made available through consulting physicians to every area in the state. Serum was rather extensively used and consequently no adequate control series is available. The fatality rate for the group whose condition was diagnosed in the preparalytic stage was 3.5 per cent. No conclusions have been reached with regard to the efficacy of the human convalescent serum which was used so

extensively that only 73 patients out of a total of 1,559 did not receive the serum.—F. W. Laidlaw, *Poliomyelitis in the State of New York in 1931*, *J.A.M.A.*, 99: 1053 (Sept. 24), 1932.

Baltimore—The general death rate in Baltimore in 1931 was 14.16, slightly higher than that for 1930 but with this one exception the lowest death rate since 1921. The infant mortality rate was 74.5. The Health Department suffered a reduction in its appropriation for 1932 of 20 per cent over the 1931 budget allowance. This required the laying off of 93 members of the staff. There were immunized against diphtheria 16,239 children of which number 6,400 were treated in the preschool clinics, 7,839 in the school clinics and

2,000 by private physicians. There were reported 416 cases of diphtheria with 23 deaths, a death rate of 2.8 per 100,000 population.

There is reproduced in this report a copy of an abstract of the bill of mortality for the city of Baltimore for the year 1815. In that year there were 1,349 deaths. Consumption was the most important cause with 218 deaths. This was followed by cholera morbus with 167 deaths; 108 deaths from pleurisy and 98 deaths from fits. It is of interest to note that there were only 3 cancer deaths recorded, 1 death from hives, 9 deaths from teething, and 75 deaths from worms. "Sudden" death accounted for 9 and "mortification" was responsible for 5 deaths.—*Annual Report*, Baltimore Dept. of Health, 1931.

## LABORATORY

### AN ACCURATE METHOD OF READING THE KAHN REACTION

HENRY C. READ, JR.

*Read Pathological Laboratory, Fort Smith, Ark.*

ONE of the most important steps in the technic of the Kahn reaction for syphilis is the correct reading of weak positives. I have overcome this difficulty in our laboratory by means of the following apparatus. A small compound microscope (shown in Figures I and II) manufactured by Bausch and Lomb Optical Company, and known as the "Little Gem," is used. The base of the microscope carrying the mirror is detached. A small electric light with carbon filament is encased in a metal box with daylight filter. The box is made fast to the underneath side of the stage by means of screws. A rack made of copper wire, to hold one Kahn tube, is

Figure I—Front View

attached to the stage in such a manner as to be between the objective and the source of light. The whole is then mounted on a stand and the microscope tipped nearly to the horizontal. The source of light is just close enough to the tube to allow the small amount of heat radiated to keep the floccules in motion, and produce a boiling appearance. Thus it is very easy to distinguish between floccules and artifacts in the glass tube when focusing the microscope for reading.

The negative reactions show no flocculation. However, there may be an occasional dust particle or other piece of debris present. With a little experience these can be distinguished easily from the true floccules, for the former are rather large in size, approaching black in color and with rather even edges.

The one plus reactions take on the appearance of many minute individual grains of sand. In the two plus reactions the grains of sand seem to have banded together making them appear much larger than in the one plus. The three and four plus reactions can be read

with ease without the aid of the microscope, because of the heavy flocculation. Under the microscope the floccules take on a leafy appearance.

Figure II  
Side View. Note proximity of tube to light.

The advantages gained from reading Kahn reactions by this method are: (1) The weak positive results are brought out more clearly, and (2) there is a constant intensity of light, thus reducing a variable factor and making it feasible to read reactions at night.

## VITAL STATISTICS

Comparison of Vital Statistics for Tasmania in 1930—The birth rate per 1,000 population in Tasmania was 22.10 for the year 1930, which was practically as low as it has ever been, and compares with an average rate of 24.83 per 1,000 for the decade 1920–1929. The average rate for the 3 years 1919–1921—10 years before—was 26.73 per 1,000.

During 1930 there were 1,948 deaths registered, as compared with 2,176 in 1929, which is the lowest number recorded since 1926. The improvement was chiefly in the rural districts where there were 195 fewer deaths in 1930

than in the previous year. In the urban areas also there was a small net decrease of 33 deaths. The general death rate per 1,000 persons for Tasmania in 1930, 9.00, is the lowest ever recorded for Tasmania. The death rate in 1929 was 10.18. This rate was abnormally high; consequently there is little gratification in using the year 1929 for comparison with the more favorable results in 1930. A more valid comparison is obtained by taking, as a basis of comparison, the results for the previous decade. During the decade 1920–1929 the average number of deaths each year

was 2,074, the death rate being 9.75 per 1,000 persons living, whereas, during 1930 the number of deaths was reduced to 1,948—a rate of 9.00 per 1,000.

The number of deaths under 1 year of age (242) was smaller in 1930 than in any other year, except in 1926 when it was 232. When taken in relation to the number of births subject to the risk of death the rate per 1,000 was 50.6 in 1930, against the best rate of 46.5 per 1,000 in 1926. The average rate for the 10-year period 1920–1929 was 58.6. During 1930 there were 155 stillbirths registered, representing 3.1 per cent of all births, compared with a decennial average (1920–1929) of 3.0 per cent.

The number of marriages registered during 1930 was 1,450 against 1,712 in 1929 and 1,499 in 1928. The marriage rate per 1,000 persons, which had been increasing from 6.79 in 1926 to 6.82 in 1927, 7.07 in 1928, and 8.02 in 1929, declined in 1930 to 6.71, which is the lowest marriage rate recorded since 1918, when the rate was 5.71.—*Statistics of the State of Tasmania*. Commonwealth Bureau of Census and Statistics, 1930–1931, pp. 11–13.

**Vital Statistics of Egypt**—Egypt, in spite of the invasions it has experienced throughout the ages, shows in certain elements of its population a really remarkable racial purity for the last 6,000 years or so. The Copts of Upper Egypt are, indeed, the direct descendants of the ancient Egyptians as the tombs and paintings of the age of the Pharaohs reveal them to us. Their religion, respected by the Mohammedan conquerors of the country (in the 7th century), has enabled them to keep all their racial characteristics by preventing their fusion with the Arabic elements, which have been specially important in number since the 11th century.

The numbering of the population probably dates back farther in Egypt than in any other country, since the ear-

liest enumeration took place under the most ancient Pharaonic dynasties. Under Amasis II, before the Persian conquest, the population was numbered every year. Unfortunately, the sequence was broken, and in modern times the first computation of the population was made during the French expedition in 1800, when the population was 2,460,200. Other estimates followed in 1821, 1846, and 1873, but it was only in 1882 that a census, as understood nowadays, was carried out. At this time, the population of Egypt numbered 6,831,131.

In addition to the settled population, the Egyptian censuses cover a nomadic Bedouin population whose number is known only approximately (97,381 in 1882, 32,663 in 1917 and 35,500 in 1927).

At the 1927 census, the settled population was distributed as follows: according to nationality—Egyptians 13,952,264, foreigners 225,600; according to religion—Mohammedans 12,929,260, Christians 1,181,910 (including 946,393 Copts), Jews 63,550, other religions 3,144; and according to sex—7,058,073 men and 7,119,791 women. This excess of females is particularly remarkable in a country with a Mohammedan majority (99 men for 100 women).

The registration of births and deaths, practised by health officers and mayors since 1846, became compulsory in 1891. The obligation was then extended to foreigners on August 11, 1912. Births must be recorded within a fortnight. The birth rate is high, varying between 40 and 45 per 1,000 inhabitants (43.7 per 1,000 in 1929). The general mortality is also high, varying between 25 and 29 per 1,000 (27.3 per 1,000 in 1929). The average excess of births over deaths is about 17 per 1,000 (16.4 per 1,000 in 1929).

The increase would be still higher if the infant mortality were not so very high. From 1919 to 1929, it varied between 128 and 159 per 1,000 births.

Nevertheless, these figures are probably inferior to the actual numbers, as certain deaths of female infants occurring in the country escape registration. The infant mortality is markedly higher in the large towns. Among the native population of Cairo, it averaged 289 per 1,000 during the period 1915-1919 and 232 per 1,000 during the period 1925-1929.—League of Nations. *Monthly Epidemiological Report*, the Health Section of the Secretariat, 5-6:10-11 (May-June), 1932.

**Vital Statistics for Germany, 1931**—According to a report from the federal bureau of health, the live births in Germany for the year 1931 show a decrease of about 96,000 over 1930. This decrease is significant particularly in view of the steady decline in births which has been going on in recent years. To each 1,000 women of child-bearing age there were, in 1913, 116.5 living births; in 1930, 67.2; and in 1931, 61.8. According to statistics for the first quarter of 1932, the decline in the birth rate is continuing. In contrast with the previous years, the decline in births for 1931 was most marked in the communities with less than 15,000 inhabitants.

The number of deaths in 1931 showed an increase of 15,000, notwithstanding the fact that the reduction in births led one to anticipate a decrease of about 8,650 deaths. The infant mortality for 1931 was 0.1 below that of 1930. There are as yet no federal statistics on the chief causes of death in the year 1931. The Prussian statistics, however, which extend through the third quarter of 1931, give information on the more important causes of death, and especially on the increase of mortality in the first quarter of 1931. This increase was caused chiefly by the prevalence of influenza and disorders of the respiratory and circulatory organs.

Aside from the increase in the number of cancer cases due to the greater aver-

age age of the population, the mortality figures for 1931 were not unfavorable. There was a marked decline in the mortality from acute infectious diseases, including puerperal fever, diseases of the digestive tract, accidents and, to a slight extent, from tuberculosis. The suicide rate showed a slight increase.—*J. A. M. A.*, 99:402-403 (July 30), 1932.

**Unprecedented Rise in the Cancer Death Rate**—While health conditions in general have been extremely favorable during the last 2 years, the death rate from cancer has been rising sharply. This is one of the very few unfavorable developments in the public health in recent years.

It is true that, for a long period of years, the cancer death rate, both among the many millions of policy holders of the Metropolitan Life Insurance Company and the general population of the country, has been increasing. But the rise has been slow in each group. During the 12-year period 1919 to 1930 the difference between the minimum crude death rate for the insured (67.0 per 100,000—registered in 1919) and the maximum (79.5—registered in 1930), was 18.7 per cent. In strong contrast with this relatively slow average rise of almost 1.5 per cent per annum in the death rate, there is shown at the end of 1931, a 7.4 per cent rise in a single year; and reports for the first half of 1932 show a further rise of 9.5 per cent over the rate for the like part of last year. If deaths from cancer continue to occur at the present rate throughout 1932, the cancer death rate among Metropolitan Industrial policy holders will have increased more than three-fourths as much, in 2 years, as it did in the preceding 12 years back to 1919.

It cannot be determined at present whether the cancer mortality rate rose as sharply in 1931, among the population at large, as it did among insured

wage earners and their dependents. Unfortunately, only fragmentary and inconclusive mortality data for 1931 are, as yet, available from official sources. Nevertheless, the few reports that have been received strongly suggest that cancer deaths increased last year in the country at large, to an extent that has not been heretofore observed in any single year—although the rise was not as marked as among the working classes. According to provisional mortality reports from the States of New York and New Jersey, the cancer mortality rate in 1931 increased 5.8 per cent and 6.4 per cent respectively in these two states, which comprise approximately one-seventh of the population of the country. Scattered reports from cities show per cent increases of 11.7, 9.1, 5.8, 4.3 and 2.9 in San Diego, Syracuse, Philadelphia, Birmingham and Rochester, respectively. On the other hand only average rises are shown in the States of Indiana and Wisconsin and the cities of New York and New Haven; and small declines were registered in Rhode Island and in Buffalo, Detroit and Milwaukee.

The weight of the evidence is that the cancer death toll is now increasing at a very rapid rate. It has been suggested that the unusual increase, among Metropolitan Industrial policy holders, may have been due, in part, to a change during 1931 and 1932 in the relative age distribution of lives exposed to risk, whereby a considerably larger proportion of the policy holders is now in those age ranges where cancer mortality is the highest. This thesis is not tenable, however. The facts of age distribution among the policy holders show no marked shift. Again, when the 1930 and 1931 cancer death rates are standardized for age, a large increase in the rate is found. Furthermore, no such marked increase in the death rate has been observed in the mortality from cardiac disease, chronic nephritis and cerebral hemorrhage, all of which, like

cancer, are diseases of the older ages. The heart disease death rate among the insured rose only 2.1 per cent in 1931 (as compared with 7.4 per cent for cancer), while that for cerebral hemorrhage was unchanged and that for chronic nephritis dropped 1.6 per cent.

In conclusion, some forces must have been at work since the beginning of 1931 to cause a marked acceleration in the number of deaths reported from cancer. It is by no means assured, as yet, that the actual increase in 1931 and 1932 has been as sharp as the figures indicate. There is always the possibility that part of the rise resulted from more accurate diagnoses. An eminent authority on cancer believes this to be true. Many more cases are undoubtedly being discovered through laboratory findings, operative procedures and autopsies, which are being made more often now than ever before.—*Stat. Bull.*, Metropolitan Life Insurance Co., 13:4-6 (July), 1932.

**Population Analysis by Place of Birth for the Dominion of Canada, 1931**—The census of 1931 gave a population of 10,376,786 for Canada as against 8,787,949 in 1921. This represented a 10-year increase of 1,588,837 or 18.08 per cent for the last census over the previous one. The census of 1921 gave an increase of 1,581,840, or 21.95 per cent, over the 1911 census. Of the total increase in population, shown by the last census, 1,236,511, or 77.8 per cent, was contributed by the native born, 119,298 or 7.6 per cent by persons born elsewhere in the Empire, and 232,416, or 14.6 per cent, born in foreign countries.

The per cent distribution of the population according to birth place, at each census during the past 40 years was as follows: in 1881 in a total population of 4,324,810 the native born comprised 86.06 per cent, the British born 11.07 per cent, and the alien born 2.87 per

cent. In 1891 in a population of 4,833,-239 the native born comprised 86.68 per cent, the British born 10.15 per cent, and the alien born 3.17 per cent. In 1901 in a population of 5,371,315 the native born made up 86.98 per cent of the total, the British born 7.84 per cent, and the alien born 5.18 per cent. In 1911 in a population of 7,206,643 the native born comprised 77.98 per cent, the British born 11.58 per cent, and the alien born 10.44 per cent. In 1921 in a total population of 8,788,483, the native born comprised 77.75 per cent, the British born 12.12 per cent, and the alien born 10.13 per cent; while in 1931 in a total population of 10,376,786, the native born population comprised 77.76 per cent of the total, the British born 11.41 per cent, and the alien born 10.83 per cent.

In 1931, the native born constituted 77.76 per cent of the total population of Canada as against 77.75 per cent in 1921; 77.98 per cent in 1911. In 1901 before the provinces of Saskatchewan and Alberta were organized the native born comprised 86.98 per cent of the total population of Canada. According

to the last census persons born within the Empire made up 89.18 per cent of the population as against 89.87 per cent in 1921, and 89.56 per cent in 1911. The slight decrease in the proportion of the Canadian and British born shown by the last census as compared with previous ones is attributable largely to the increase shown by the European section of the "foreign born" which advanced from a proportion of 5.23 per cent in 1921 to 6.88 per cent in 1931. The most significant decrease in the foreign born was registered for the United States born, which fell from a total of 374,022 in 1921 to 344,574 in 1931. At the last census they comprised only 3.32 per cent of the total population as compared with 4.25 per cent in 1921, and 4.21 per cent in 1911. The classifications of the foreign born population according to birth places, so far as they relate to European stocks, are based on post-war political boundaries in the last census, as well as in the previous one.—Dominion Bureau of Statistics, *Birthplaces by Sex for Canada and Provinces*, 1931, pp. 1-3. *Census Bull.* 15.

## PUBLIC HEALTH ENGINEERING

### CITY OF BRADFORD WORKS OF SEWAGE DISPOSAL

1790-1930

THIS is a pamphlet issued in 1931 (3rd ed., 92 pp.) by the Sewage Department of the City of Bradford, by its Chief Engineer, H. Wontner-Smith, describing the history, construction and operation of the Sewage Disposal Works of the City of Bradford, England. Bradford for years has been the center of the wool combing industry in England, and thereby has been confronted with the problem of handling a large amount of waste.

After various trials of precipitants, in January, 1901, sulphuric acid was used and it was found that the sludge could be filter-pressed and the grease extracted. Both grease and dried sludge cake are marketable.

The main works at Esholt serve a drainage area of 20,156 acres and a population of 273,000 people. There is also a smaller works at North Bierley, serving 3,532 acres and 23,500 people. The flow at Esholt is 63 Imperial gallons

per head per day. The average flow is 23.75 million Imperial gallons per day. There is a wide fluctuation in the hourly flow because of industry. Sewage entering the works is one-half domestic and one-half wastes, the latter consisting of wool scouring effluents and dye liquors. The former are very strong in grease and suspended matter. The yearly average analysis of the sewage handled shows in parts per million: Grease 890, Suspended matter 1,450, Oxygen absorbed 246, and Alkalinity 815.

The sewage comes to the works through a tunnel and is put through a grit catching device, is then acidified with sulphuric acid and passed through a mixing tank to two series of precipitation tanks, one containing 20 units for the acid cracking process; and the other 20 units for secondary precipitation. The tank effluent is passed through 53 acres of bacterial filters built up with coal. The sludges are screened, then pumped to the sludge disposal building, where it is treated for the extraction of grease and water. The methods of working are discussed at considerable length.

At the present time some 12,000 to 13,000 tons of acid are used per year. The sludge is held about 3 months in the tanks, arriving in the filter presses with approximately 80 per cent moisture. The acid is made by the City of Bradford, partly at the plant and partly at its gas works. The bacterial filters are made of coal, from  $\frac{3}{4}$ " to  $1\frac{1}{4}$ " in size. At the time of the general strike in 1926, some 200,000 tons were sold and afterwards replaced. Rectangular traveling distributors are used, drawn by wire ropes.

The sludge treatment is of particular interest. The sludge is heated in 7-ton vats by steam coils to 170° F. It is then forced by ejectors to 128 presses in the press house and is filter-pressed through cotton cloths by alternately feeding heated sludge and super-heated

steam to keep up the temperature. Liquid and grease are discharged in the process. About 40,000 cotton filter press cloths are used annually. A cloth lasts from 6 to 8 weeks. Ordinarily, the pressing takes 64 hours, the grease content being reduced in the dry solids from 40 per cent in the original sludge to 16 per cent; the water content being lowered to 26 per cent. The pressed cake is removed to an open air drying area, where it is kept in heaps for 12 months. This reduces the grease content by the "heating" of the material. The sludge is sold. Although various experiments have been carried on with activated sludge and sludge digestion, the present process is the one favored.

Construction of the works is described in detail and interesting data are given on the business side of the undertaking. The works have cost about £1,910,000.

During the war the sale of grease was remunerative, bringing in an income in 1918 of £126,658 sterling. In the first 12 years of the post-war period the sales produced over a half-million pounds sterling. In the years 1920 to 1930 the sale of the sludge brought in an additional total of £40,000. The sludge is also ground to powder, mixed with coal and used for stoking the boilers. The report states that the cost of sludge disposal and pressing (at present around £35,000 per annum) is more than covered by the sales in recovery of grease and manure, but that this revenue does not cover the cost of the whole treatment.

The pamphlet closes with an interesting description of the old Esholt estate, which dates back to 1086. The present offices of the department are in a very interesting and well preserved building, which is of historical interest. The entire estate, comprising 1,700 acres, was purchased, including the village and other lands beside those utilized directly for the sewage treatment.

LANGDON PEARSE

## FOOD AND NUTRITION

**Antirachitic Value of Milk from Cows Fed Irradiated Yeast**—Several workers have reported positive antirachitic properties in the milk from cows fed irradiated yeast if there is incorporated 30,000 to 60,000 vitamin D rat units per day in the yeast. Arrangements were made by the authors to secure "yeast milk" from a herd of 9 cows fed, in addition to the ration, 60,000 rat units as irradiated yeast daily.

This milk was fed to 4 human subjects—2 male infants, aged 16 and 8 months respectively, and 2 female children, 4 years, 11 months, and 3 years, 2 months, respectively, all of whom had definite active rickets as evidenced by roentgenograms. The milk was pasteurized for 3 of the patients and for the 4th it was in addition boiled for 5 minutes. Clinical records of these 4 showed definite progress toward healing of the rickets.

Analyses of the serum-calcium and serum-phosphorus show an increase in the former and a marked increase in the latter after the addition of the special milk. Deposition of bone as shown by roentgenograms was established after 2 weeks on the special milk diet. It has been stated by Howland and Kramer (*Tr. Am. Pediat. Soc.* 34: 204, 1922) that the determining factor in calcification of bones is a figure between 30 and 40, representing the product of the concentration of calcium and phosphorus in milligrams per 100 c.c. of serum. At the beginning of the feeding period the concentration in all cases was definitely under 30, and at the end of the period it varied from 58.8 to 69.4. The authors conclude that there is calcium deposit in the concentration of 30 but that the concen-

tration which permits complete calcification depends upon the rate of growth of the individual.

The opinion is advanced that the administration of antirachitic vitamin in the form of yeast milk is preferable to adding it to food as a therapeutic agent. After 5 minutes' boiling the milk still possessed antirachitic properties.—Edwin T. Wyman and Allan M. Butler, *Am. J. Dis. Child.*, 43:1509 (June), 1932.

**Seasonal Variation in Antirachitic Action of Arkansas Sunshine**—Biologic determinations of the antirachitic action of sunshine have been made a Little Rock at all times of the year with large groups of animals under carefully controlled conditions. The average daily amount of sunshine necessary to afford the same partial protection against rickets in rats receiving a rachitic diet varied from 5 minutes in May, June, and July to 168 minutes in December, with intermediate values for the other months.—Paul L. Day, *Am. J. Dis. Child.*, 43:1455 (June), 1932.

**The Effect of a High Intake of Manganese on the Growth of Rats**—This investigation was made on rats before weaning and after weaning. The basal ration used throughout the experiment was that described by Waddell & Steenbock (*J. Biol. Chem.*, 80:431, 1926), and contained 13.4 mg. of manganese per kilo. Female rats which received 10 mg. of manganese per day above that in the stock ration (13.4 mg. per kilo) were as successful in rearing their young as females receiving the stock ration only.

The addition of  $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$  equiv-

alent to 2,000 p.p.m. of ration did not retard the growth of rats over a period of 12 weeks immediately following weaning. Therefore, the slower growth of rats on a modified ration containing added manganese, reported in a previous publication (*J. Biol. Chem.* 90: 65, 1931), was not due to toxicity of this element but to a less suitable source of milk solids.—J. T. Skinner, *J. Nutrition*, 5:451 (Sept.), 1932.

**The Effect of Figs and Small Amounts of Raisins on Urinary Acidity**—In a previous experiment (*J. Nutrition*, 5:103, 1932), the effect of fresh Malaga grapes, several kinds of grape juices, grape concentrates and 2 varieties of raisins on the urinary acidity was shown. This experiment was undertaken on male subjects to ascertain the effect of raisins and figs. Thompson Seedless raisins and Calimyrna white figs were used. The experiment were of 11 to 12 days' duration.

Each experiment was divided into two periods. For the first 5 days each person received only the basal ration; during the next 6 or 7 days each person received, in addition to the basal ration, a constant quantity of raisins or figs. When the raisins or figs were added to the basal diet, the following results were observed:

A ration of 105 gm. of raisins in bread produced 50 per cent to 60 per cent as great an increase in the pH of the urine as did 300 gm. of raisins. The increase produced by the 105 gm. ranged from 0.45 to 0.60 pH units. Three hundred gm. of figs produced an increase in the pH of the urine ranging from 0.9 to 1.1 pH units. This change was slightly greater than that produced by an equal weight of raisins.

A decrease in the ammonia excreted with a corresponding decrease in the total acidity was noted. The 300 gm. of figs produced a greater decrease than 105 gm. of raisins and also a slightly

greater decrease than an equal weight (300 gm.) of raisins.

There was an increase of the alkaline reserve above the normal for each subject, the greater increase being produced by the figs.

A correlation between the alkalinity of the ash and the physiological reaction was apparent. A more basic body reaction was associated with higher alkalinity of the ash.

The organic acids from 105 gm. of raisins daily were completely oxidized by the body, whereas those from 300 gm. were only 99.8 per cent oxidized. However, the organic acids from 300 gm. of figs were oxidized to the extent of 97.5 per cent.—Lawrence G. Saywell, *J. Nutrition*, 5:519 (Sept.), 1932.

**The Administration of Ferrous Iodide and Linoleic Acid to Rats Deprived of Vitamin A**—Male rats, weighing 38 to 50 gm. at 21 days of age, were given *ad libitum* a diet consisting of extracted casein 70 per cent, starch 20 per cent, yeast 5 per cent, salt mixture 4 per cent, and sodium chloride 1 per cent. This diet was supplemented daily with 0.001 mg. of irradiated ergosterol dissolved in oil. When the rats ceased to grow and developed severe xerophthalmia, which occurred in about 40 days, they were divided into 5 groups which received, respectively, daily supplements of 0.1 c.c. distilled water; 1 drop cod liver oil plus 0.1 c.c. distilled water; 0.1 c.c. ferrous iodide solution; 0.1 c.c. of linoleic acid; and 0.1 c.c. of ferrous iodide solution plus 0.1 c.c. of linoleic acid. All rats were examined at death for infections of the middle ears, of the glands at the base of the tongue, and of the salivary glands, as well as for renal and bladder calculi.

The administration of ferrous iodide and linoleic acid, alone or in combination, was ineffective, either for promotion of growth, the cure of xeroph-

themia, or as a preventive of infection or renal disturbance in rats deprived of vitamin A. At autopsy one or more of the typical lesions, associated with vitamin A deficiency, was found in all the rats that did not receive cod liver oil.—Lucille L. Reed, L. B. Mendel, and Hubert B. Vickery, *Science*, 76:300 (Sept. 30), 1932.

**The Viability of *Lactobacillus Acidophilus* as Affected by Freezing in a Sherbet Mixture**—To increase the palatability of *L. acidophilus* milk, it was sweetened, flavored, and frozen into a sherbet. Twenty-eight sherbets were prepared and a study made of the numbers of viable organisms remaining after 1, 2, 3, 5, and 7 days of storage at temperatures below  $-17^{\circ}\text{C}$ . Four strains of *L. acidophilus* were used in the preparation of the sherbets.

A variation was found in the viability of these strains when exposed to the conditions prevailing in such a frozen product. The numbers of viable organisms in sherbets carrying strain A organisms were reduced to only a few million per c.c. after 5 days' storage, while under similar conditions several hundred millions of viable organisms were usually present in the sherbets carrying the other strains of *L. acidophilus*. A variation in viability was found to occur in cultures of the same strain. Whether or not this variation was due to the age of the cells or some combination of factors was not determined.

A number of these sherbets were prepared so that they differed in reaction only. A more rapid reduction of organisms was found to occur in the sherbets of the higher titratable acidity. The sugar concentration, as it was varied in the sherbet mixtures, causes no significant variation in the viability of the organisms. It was possible to prepare sherbets in which large numbers

of organisms remained viable after 5 to 7 days of storage at temperatures below  $-17^{\circ}\text{C}$ . when the more resistant strains of *L. acidophilus* with a high initial count were used and the titratable acidity was not permitted to become excessive, preferably not in excess of 1.10 per cent.—Chas. C. Prouty and H. A. Bendizen, *J. Dairy Sci.*, 15:413, (Sept.), 1932.

**The Toxicity of Ethylene Oxide**—A concentration of 1:400 ethylene oxide was put in a small chamber and breathed by 4 men. It had a pleasant acetic acid-like smell, was slightly irritant to the nasal passages, but produced no after-effects. A concentration of 1:80 had a definite irritating effect on the nasal passages in 10 sec. There was no lachrymation. The liquid placed on skin boils, at once evaporates, leaving no mark, irritation, or erythema. One drop placed in the eyes of rabbits showed sharp conjunctivitis with blepharitis, but the condition subsided rapidly to normalcy in 4 days, and there was no permanent damage to the eyes. Intravenous injection in rabbits, 175 mg. per kg. body weight, proved fatal in 6 hours.

Early symptom was diarrhea and after 4 hours fine tremors of the limbs, the stance was wide and the feet splayed with the head dropping on the floor. Respiration was regular but somewhat hurried. Nystagmus was present and there was incoördination of limbs and jaws, followed by convulsions. Between convulsions the animal lay helpless and unable to hold up head or support body on legs; all the muscles were lax and toneless. A dose of 146 mg. per kg. body weight produced no symptoms beyond diarrhea and dislike of movement. A dose of 133 mg. per kg. was given and repeated after 20 hours.

Following the first dose, the animal showed wide stance, with fine muscular

tremors. The second dose caused death during the night. A dose of 85 mg. per kg. was given and repeated after 43 hours and again in a further 48 hours. After the first dose, there was nothing abnormal; after the second, convulsions followed by recovery; after the third, convulsions and death. Autopsy findings in these animals were congestion of all organs with catarrhal changes in kidney tubules and small numerous submucous hemorrhages in stomach.

A concentration of 1:80 for 30 minutes proved fatal to mice, rats and guinea pigs. Post-mortem changes were marked damages throughout the body. Concentrations varying from 1:80 to 1:150 for single exposures and from 1:80 to 1:800 in repeated exposures were used. In the concentration 1:80 for 30 minutes, all mice (3) were dead in  $2\frac{3}{4}$  hours, the rats (3) were all dead in 6 hours, having become markedly dyspnoeic, two were destroyed after 7 hours and the third survived; all rabbits had slight weakness of hind legs and were killed three days after exposure. Autopsy findings were the same as before.

A concentration of 1:100 for 30 minutes proved fatal to rats and mice, and 1:150 proved fatal to mice only, the effects on other animals being in proportion to those noted for 1:80. All single exposures in small concentrations produced like effects.

From feeding rats with vapor contaminated food, the authors conclude that enough ethylene oxide was retained from an atmosphere filled with ethylene oxide by the foodstuffs (bread, butter, margarine, boiled fat bacon, cheese and oatmeal) to render them dangerous to health at least. No class of foodstuff has escaped suspicion entirely. When sprayed on food this substance is highly dangerous. Ethylene oxide injected intravenously in a fatal dose causes a drop in blood urea from normal 42 mg. per 100 c.c. of blood to 33 mg.

per 100 c.c. Damage to kidney is sufficient to cause death.—W. J. Greaves Walker and C. E. Greeson, *Brit. J. Hyg.*, 32:409 (July), 1932.

**Do Children Who Drink Raw Milk Thrive Better Than Children Who Drink Heated Milk?**—During the past few years, raw milk advocates have contended that heating milk adversely affects its healthfulness and growth-promoting capacity, drawing their conclusions from experiments conducted at the Ohio State University, (*Jersey Bulletin and Dairy World*, Feb. 11, 1931), and the British National Institute for Research in Dairying (*Lancet*, Mar. 21, 1931). Extensive studies were made by the U. S. Public Health Service in coöperation with the health departments of ten states.

Studies were made of 3,700 children, ranging from 10 months to 6 years of age. There was no significant difference between the average weight of children who received no milk except raw milk for more than the latter half of their lives. The weights were 33.6 and 33.2 lb., the difference being in favor of heated milk. The heights were 37.5" and 37.4", the insignificant differences being in favor of heated milk.

There was no material difference between the two groups of children from the standpoint of the relative percentage of life during which various supplementary foods were included in the diet, except in the case of cod liver oil, which was included during an average of 41.6 per cent of the lives of the children receiving heated milk, and an average of only 27.6 per cent of the lives of the children receiving raw milk. This difference did not, however, affect the relative positions of the two age-weight curves significantly, since the average weight of the 636 children in the heated-milk group who received no cod liver oil at all was 33.5 lb. as compared with 33.8 lb. for the 794 children in

the heated-milk group who received cod liver oil during more than half of their lives. The parents of the children receiving predominately raw milk reported a higher incidence of diphtheria, scarlet fever, intestinal disturbances, and rickets than did the parents of the children receiving heated milk only.

The two groups of children were divided into 3 major race groups, Anglo-Saxon, Latin and miscellaneous, but the age-weight and age-height curves were not materially affected by the race dis-

tribution. It is concluded from this study that the growth-promoting capacity of heated milk plus the supplementary diet received by the average American child of 10 months to 6 years is not measurably less than the growth-promoting capacity of raw milk plus the supplementary diet received by the average American child of 10 months to 6 years.—Leslie C. Frank, F. A. Clark, W. H. Haskell, M. M. Miller, F. J. Moss and R. C. Thomas, *Pub. Health Rep.*, 47:1951 (Sept. 23), 1932.

## INDUSTRIAL HYGIENE

**The Manufacture of Linoleum—**A historical and geographical introduction is made of the linoleum industry which in 1929 in the United States had 7 establishments, 5,544 employees and value of products amounting to \$57,250,449. The gross sales in Canada amount to approximately \$15,000,000 a year.

The actual plant conditions are described for two plants, particularly a description of the processes. The potential health hazards considered to exist consist of linseed oil (containing lead), cork dust and benzol, with a number of others described elsewhere in literature. There is also a job classification made which points out the chief hazards in each occupation in the industry.—Retail Credit Company, *Industry Rep.*, 7, 2: 11–21 (Feb.), 1932. E. R. H.

**Some Dust Hazards of Industry, With Particular Reference to Silicosis—Also, The Very Least an Employer Should Know About Dust and Fume Diseases—**The first of these is a 15 pp. pamphlet which summarizes from literature the chief features about siliceous dust and silicosis. The second is a small 8 pp. pamphlet devoted to

the subject in the title with a further discussion of what constitutes reasonable care against the effects of dust and fumes. (These two pamphlets are commendable statements of the case by The Willson Products, Inc., manufacturers of respirators and protective equipments.)—Frederick Willson, M.D., Reading, Pa., 1932.

**Safety in the Manufacture and Use of Acetylene—**The paper describes technical processes in the manufacture and use of acetylene and the incidental accident risks, also legislative measures adopted in various countries for the prevention of accidents. Tests and experiments are included.—International Labour Office, World Peace Foundation, 40 Mt. Vernon St., Boston. 6 shillings. E. R. H.

**Hardening Procedures and Upper Respiratory Disease (Common Cold)—**Author's summary:

1. Over 300 adults were observed for 35 weeks from September 29, 1929, to May 31, 1930, when every effort was made to secure reports of all attacks of upper respiratory disease (common cold).

2. The group that during the winter slept with windows partially open, and the group

that slept with windows wide open showed no significant difference in respect of (a) frequency, and (b) severity of attack of upper respiratory disease (common cold). In respect of type of attack it was found that of the two groups the second (wide open windows) suffered relatively (a) fewer attacks with coryza and sore throat, and no cough (Cor+C—ST+), (b) more attacks with coryza, cough, and sore throat (Cor+C+ST+), and (c) more attacks with cough.

3. The group that exercised outdoors less than 8 hours per week in the summer, and the group that exercised 8 or more hours per week, showed no significant difference in respect of (a) frequency, (b) severity, and (c) type of attack of upper respiratory disease (common cold).

4. The group that exercised outdoors less than 4 hours per week in the winter, and the group that exercised 4 or more hours per week, showed no significant difference in respect of (a) frequency, (b) severity, and (c) type of attack of upper respiratory disease (common cold).—

### Dermatitis and Compensation to Workmen—

Sir Vivian Henderson asked the Home Secretary whether there had been an increase or a decrease in the number of cases of dermatitis in the last 3 years for which compensation had been paid; and whether any steps were taken by his department to encourage the wearing of gloves or mittens in appropriate cases. Sir Herbert Samuel replied: "The Workmen's Compensation Statistics for 1928, 1929, and 1930 (which is the last year for which figures are available) show an increase in the number of cases. There were 1,170 cases in 1928, 1,405 in 1929; and 1,499 in 1930."

Various steps have been taken by the department to enforce or encourage the wearing of gloves as a precaution against dermatitis. For example, gloves are required for persons employed in various processes under the Chemical Works Regulations of 1922, and the Chromium Plating Regulations of 1931, and under the Welfare Order of 1918 for use of bichromate potassium or sodium in dyeing, the Hollow-ware and Galvanising Welfare Order of 1921, and the Tanning Welfare Order of 1930.

Further, a general leaflet providing information as to the causes of dermatitis and recommending precautions, including the use of gloves, has been prepared and widely dis-

tributed among occupiers of works likely to be affected, and, with a view of securing the coöperation of the workers, a form of cautionary notice which can be exhibited in the workrooms has been issued and put on sale through the Stationery Office. Reference is also made to the value of gloves in certain special memoranda dealing with the prevention of dermatitis in particular processes.—

*Med. Off.*, 1232:100 (Mar. 5), 1932.

E. R. H.

**Air Conditions and the Comfort of Workers**—The importance of air conditions to the comfort, health and efficiency of workers is stressed, while the temperature standards for comfort in relation to humidity and air movement are described for both winter and summer conditions.

The methods of measurement of physical properties of the air with an illustration of the sling psychrometer, the anemometer, and the kata-thermometer are given. "Conditioned air" is discussed and "effective temperature" while the latest designed "comfort zone" chart is exhibited and explained. There is a synopsis of the effects of high atmospheric temperatures on man, a brief description of the methods of removal of excessive heat and moisture and the nature of what constitutes "air cleanliness." — Policyholders Service Bureau, Metropolitan Life Insurance Co., New York, *Indust. Health Series* 5, 20 pp., 1932.

E. R. H.

### Carbon Monoxide, Acute and Chronic Poisoning and Experimental Studies—Authors' conclusions:

We admit that this is but a preliminary step in any study of this interesting subject but it does seem from our findings that CO is not rapidly eliminated from the body unless other measures than simple respiration of air are used.

It appears that in acute cases death is caused entirely by anoxemia and respiratory failure.

The body after death is capable, even after embalming, of absorbing sufficient carbon monoxide, when concentrated and with sufficient time of exposure, to produce all of the

macroscopic appearances and positive chemical findings of death due to this gas.

It is also possible to produce similar findings by injecting the body with either laked or whole blood, saturated with CO. These possibilities are of grave medico-legal importance.—

*J. Lab. & Clin. Med.*, 17, 5:415-427  
(Feb.), 1932. E. R. H.

**Bakers' Dermatitis from Activators Containing Persulphates—**  
This illustrated article is summarized by the author as follows:

An outbreak of dermatitis among bakers employed as dough makers occurred in New South Wales in 1929-1930. Over 50 cases were recorded—about 1 man in every 20 of those employed in dough making was affected by a papuloerythematous rash of hands, forearms, arms, neck and sometimes the lower extremities and the groin which cleared up on leaving work but recurred on returning.

Cutaneous tests showed that individuals who suffered from or who had been affected by dermatitis were sensitive to ammonium persulphate, an ingredient of yeast foods, or activators used, and that they were generally of a susceptible or allergic type. Removal of persulphate from these activators practically abolished the incidence of the disease.—

Charles Badham, Studies of Industrial Hygiene No. 16, Section I.-E. *Report of Director-General of Public Health, N.S.W., for year ended Dec. 31, 1930*, 71-76. E. R. H.

**The Printing Industry—**The printing, publishing, and allied industries in the United States was composed in 1929 of 24,369 establishments employing 280,908 wage earners who drew wages of \$596,142,000 and the value of products was \$2,760,945,000. Canada has also an extensive industry in this line with Toronto as the center.

Hygienic conditions are described for several typical plants with a description of processes in type printing, lithography, rotogravure, steel engraving, and photo-process engraving.

A description of the potential health

hazards includes excerpts from *Industrial Health-Hazards and Occupational Diseases in Ohio*, and from *Hygiene of the Printing Trades*, the latter a Bulletin of the U. S. Labor Statistics, 1917, by Dr. Alice Hamilton and Charles H. Verrill. Next follows a classification and an index of jobs which cites the chief health hazards of each. This is an industry involving accidents, noise, physical strain, monotony, sedentary work, postural hazards, glare and eye-strain otherwise, burns, acid burns, dermatitis and exposure to a considerable list of poisons depending upon the given process.—*Industry Report*, Retail Credit Co., Atlanta, Ga., 7, 3:23-37 (Mar.), 1932. E. R. H.

**Lacquers and Their Hazards—**The term "lacquer" is derived from the lac tree found in the East Indies. The present article is limited to coating products in which nitro-cellulose is the base. Such are also called pyroxylin lacquers. They are applied by the spray gun and dip tank, which have practically replaced the hand brush.

The ordinary lacquer contains 5 basic ingredients:

Nitro-cellulose (or nitro-cotton) gives water-proofness, hardness and durability to the coating.

Solvents and diluents for dissolving the nitro-cellulose and gums give quick drying properties, as well as preventing the finished film from blushing or turning white.

Gums or resins to thicken the coated film and add to its adhesive properties.

Softeners or plasticisers to overcome brittleness.

Pigments or coloring material to give color to the finish and also to reflect the actinic rays of sunlight, thereby making the coating more durable under outside exposure.

A diagram shows the percentage composition of an average lacquer—82 per cent of which is composed of volatile substances.

The amount of volatile matter constitutes the main hazard, with the diluents and solvents by far the most

important since these may consist of benzol, toluol, xylol, petroleum naphtha, and various olefine acetates, ethers, alcohols, etc. The evaporation rate of some of these is described as well as their toxic properties, some of which are cumulative. In addition, new solvents and combinations are constantly being placed on the market. There is a special discussion on ventilation and fire prevention.—William J. Burke, *Indust. Bull.*, New York Dept. of Labor, Albany, 11, 7:223–225 (Apr.), 1932. E. R. H.

**Silicosis and the Industrialist—**This article is by the managing director (technical) of Lever Brothers, Ltd., soap manufacturers, and discusses briefly points of historical interest as well as pathological features and other impressions brought out at the Johannesburg Conference in 1930.

In Great Britain the criterion of safety in the Workmen's Compensation Schemes goes no further than the composition of the mineral substance itself, e.g., the concentration of the  $\text{SiO}_2$  therein is not referred to. Thus, the Refractories Industries Scheme does not apply if the mineral contains less than 80 per cent total silica. In the Sandstone Industry the figure is 50 per cent. In America it is customary to gauge the risk on the number of particles of free silica per cu. ft. of air, irrespective of the other constituents of the dust. In South Africa the total number of mineral particles per cu. ft. is taken as the basis. Thus international agreement as to methods of estimating is much to be desired.

The fact that finely ground silica enters into the composition of many widely used household articles (such as soaps and cleansers) broadens the picture. The equipment for protective purposes in the company's plant at Port Sunlight bulks more largely to the eye than the operating plant itself. No

case of silicosis has yet occurred in any of the company's factories.—Horatio Ballantyne, *J. State Med.*, 40, 6:342–349 (June), 1932. E. R. H.

**Silicosis in Pottery Industry—**Mr. Wedgwood asked the Home Secretary the number of compensation claims made and the number granted, and the fatalities recorded, in the pottery industry since the silicosis order came into operation. Mr. O. Stanley replied: "I regret I have no information as to the number of compensation claims made, but the number of cases in this industry in which compensation was paid since February 1, 1929, when the Various Industries (Silicosis) Scheme came into operation, up to the end of 1931, is 322, including 87 fatal cases.—*Lancet* (London), 5681:160 (July 16), 1932.

E. R. H.

**Asbestos Industry Regulations, 1931—**This large sheet for posting in work places, etc., designates the industry and work processes covered, definitions, and duties. The latter refer in Part 1 to occupiers (employers), and in Part 2 to persons employed. There is a footnote referring to breach of regulations and the posting of same in conspicuous places.—Herbert Samuel, One of H. M. Principal Secretaries of State, Dec. 31, 1931. (Purchasable from British Library of Information, 270 Madison Ave., New York, price 1d. net.)

E. R. H.

**Fibrosis of the Lungs in South Coast Coal Miners, New South Wales—**Author's summary:

At the request of the Royal Commission on the Coal Industry in New South Wales (1929), a radiographic examination was made of the chests of a number of coal miners and a clinical examination of a smaller number.

A fine type of fibrosis of the lungs varying in degree from slight to marked was found to be present in 122 of 471 (25.9 per cent) coal miners examined and the incidence among

men who had worked on the South Coast coal-field only was 25.0 per cent.

This radiographic fibrosis was considered to be complicated by infectious processes in 49 of the 122 cases.

Radiographic appearances of tuberculosis in the form of an acute lesion, a latent process or an old scar, were found in 24 or 5.1 per cent of the 471 men examined.

It is concluded from the radiographic findings that a fibrosis of the lungs may be caused by working in coal mines of the South Coast, that the onset is slower and the disability less marked than from the disease produced in metalliferous mines and that the estimation of disability must depend less on radiographic findings than on clinical examination. This fibrosis of coal miners should be placed on a sound pathological and chemical basis.—

Keith R. Moore and Charles Badham, *Health*, Commonwealth Department of Health, Canberra, N. S. W., 9, 5:33-43 (including tables of radiographic examinations) (May), 1931. See also Section I.-E., Division of Industrial Hygiene, *Report of the Director-General of Public Health, N. S. W., for year ended Dec. 31, 1930*, pp. 67-68.

E. R. H.

**Illness Among Button Workers—**Five cases of a condition diagnosed as yellow atrophy of the liver recently occurred at Fort Madison (Iowa) among the personnel of a button factory, with 3 fatalities. A meeting of physicians disclosed, however, that a total of 16 cases had been reported since November, 1928, with 5 deaths. All the cases had occurred in men employed in the button factory during the winter months.

The work at the plant involved consists solely of sawing blanks from oysters and clam shells, which are shipped elsewhere to be finished into buttons. The shells are obtained from Texas, Mexico and Illinois.

At a meeting of the Fort Madison City Medical Society, it was generally agreed that in view of the absence of any tangible evidence of metallic poisoning, the disease must be considered of an infectious nature. Arrangements

have been made for prompt removal to the hospital of the State University of Iowa if another case should develop.—*Medical News*, Iowa. *J. A. M. A.*, 99, 2:140 (July 9), 1932. E. R. H.

**Tumors of the Skin Produced by Blast-Furnace Tar—**From experimental procedures using mice and various samples of tar, the author found that tar obtained from a variety of blast-furnaces produces malignant tumors. It is less active than gas tars but its carcinogenic properties can be enhanced by extraction with ether. If applied too frequently, blast-furnace tar produces ulceration of the skin, but its toxic effects are not well marked, as some animals survive for 56 weeks.

It appears that workers in iron works do not handle the tar as do those in producers of gas, tar, pitch, and paraffin. This explains the absence of such tar tumors in the former.—Georgiana M. Bonser, *Lancet*, 5657:775-776 (Apr. 9), 1932. E. R. H.

**The Health of the Women in the Hatters' Furriers Trade—**No clear instances were obtained of the peculiar nervous conditions characterized by self-consciousness, shyness and irritability which feature mercury poisoning. However, in a group of 89 women, 8 complained of loss of weight, 7 of dyspnea, 6 of indigestion, 5 of sore throat, 4 with pains in muscles or joints, 4 with back-aches, 3 of sleeplessness and 2 of marked fatigue. There were 7 cases that were considered as probably showing mild chronic mercury poisoning in the condition of the gums—purplish red or mauve discoloration. There were unfavorable effects from noise and a large proportion of abnormal conditions of the nose and throat, of overweight, constipation and dysmenorrhea.—Nelle Swartz, *Indus. Hyg. Bull.*, New York Dept. of Labor, May, 1932, pp. 266-267. E. R. H.

# CHILD HYGIENE

## THE PRESCHOOL CHILD

THE conviction is growing among public health administrators that health programs for the preschool child cannot well be conceived apart from the hygiene of infancy and maternal welfare. While it may be justifiable for various reasons to intensify first upon one phase of child hygiene and then upon another, in the end the whole field must be covered adequately as an integral part of the public health.

This fact is recognized fully by the Health Organization of the League of Nations, which has issued a comprehensive report on *Maternal Welfare and the Hygiene of Infants and Children of Pre-School Age*,\* prepared by a special committee to deal with these questions. A previous memorandum issued by the League of Nations, *Enquiries Into the Causes and Prevention of Still-Births and Mortality During the First Year of Life*, has been very helpful in orienting us in this difficult sector of child life.

The present report is based on an analysis and comparison of the experience by different countries in the child health field. It emphasizes that "in considering questions of maternity and infant hygiene, it is important not to lose sight of the other branches of modern public health administration with which these are bound up."

Maternal welfare is considered under the following general heads:

- Rate of Maternal Mortality
- Maternal Morbidity
- Causes of Maternal Mortality and Morbidity
- Reduction of Maternal Morbidity and Mortality
- Abortion and Contraception

The opening paragraph on maternal welfare states,

It is beyond doubt that many maternal deaths might be avoided and that much sickness might be prevented if it were possible to secure for all pregnant and parturient women adequate medical, nursing, and domestic attention. The prevention of obstetric disaster is not an altogether simple problem. It depends partly upon the professional skill of the doctor and midwife; partly, on the provision of facilities, such as hospital accommodation, medical or nursing attention, etc., for the patient unable to secure these for herself; and to no small extent upon the willingness and intelligence of the patient in seeking and following such advice as is available for her.

Reduction of mortality and morbidity is summed up as follows:

The causes of maternal mortality and morbidity being partly social and partly medical, it follows that measures which may serve to reduce sickness and death among mothers must be such as will improve the medical and nursing services for maternity, and will also educate the woman and her friends to realize the value of early, frequent and continuous supervision, careful treatment and efficient obstetric assistance. These measures may be divided into:

- (a) Medico-social enactments for the protection of maternity
- (b) The provision of facilities for supervision and treatment
- (c) A high standard of professional education for the doctor and midwife, so as to insure suitable obstetric attention
- (d) The education of public opinion

Especial attention must be given to the prevention and treatment of abortion if the maternal mortality rate is to be substantially lowered. The report succinctly states that,

A threatened abortion often receives no proper medical attention, especially if the woman herself attempted to interrupt pregnancy, and the doctor is frequently not summoned unless acute septic infection intervenes.

\* Obtainable from the World Peace Foundation, 40 Mt. Vernon Street, Boston, Mass. Price, \$.50.

Cases of abortion are not usually welcome in the maternity hospital because of their potentially septic character, and increased hospital accommodation is urgently needed for these cases, so that the uterus may be properly emptied if the abortion is inevitable, and suitable after-treatment provided. Instruction should be given at the prenatal clinic as to the dangers of abortion and the importance of seeking medical advice should it occur.

Infant welfare is discussed logically, beginning with measures directed toward the reduction of stillbirths and neonatal mortality which, despite all that has been done, remain unduly high.

Infant welfare is governed by certain general principles, though the precise measures taken to reduce infant mortality must be adapted to the existing customs, to the existing standard of public health, and to economic possibilities. In determining these principles, due account must be taken of the infant mortality rate in the district under consideration; the importance of this index was shown very clearly by the inquiry into infant mortality carried out in different countries in Europe and South America under the auspices of the League of Nations Health Organisation. A detailed study of the causes of stillbirths and infant mortality is contained in the reports drawn up as a result of this inquiry (*documents C.H.820 and C.H.908*[1]).

The following account is based on the experience gained in the course of that inquiry, and is intended for those countries, or rather those regions, having infant mortality rates approximating to the rates found in the districts covered by the inquiry; these rates vary from 50 to 200 per 1,000 (*i.e.*, 50 to 200 deaths under 1 year per 1,000 live births), and to these must be added stillbirths, varying from 23 to 64 per thousand live births.

Infancy must be protected against three main dangers: congenital and developmental defects, alimentary disturbances and infective disease. The first of these accounts for nearly all stillbirths and for deaths in the first 7 days of life, and as deaths in these two groups are generally attributable to similar causes, they may usefully be considered together. The other two conditions chiefly affect older infants. "Infection" covers acute or chronic infections, whether local or general, specific or

otherwise, and in this connection diseases of the respiratory passages are most important. Lastly, alimentary disturbances cover deaths due to faulty methods of feeding, which may or may not be associated with disease of the digestive system.

Due consideration is given to preventive measures, nursing care, infant welfare centers, homes for mothers and babies, boarding out of babies, and milk. The statement concerning slum destruction is particularly timely.

The importance of slum demolition is by no means confined to the sphere of infant mortality, but nowhere is its urgency and its efficacy more apparent than in this particular field, urban and rural slums both playing the same fatal part. Cold, heat, darkness and the absence of ultra-violet rays have a disastrous effect on the infant's health.

From a constructive standpoint, it may be added that, in the towns, the erection of workers' tenements where the children are crowded together, thus increasing the risk of infection for the younger ones, is not as satisfactory as the establishment of garden cities, where infants can more easily be isolated—at least, to some extent.

A considerable portion of the report is given to the health of the preschool child. The dangers of this period are clearly pointed out. Problems of nutrition, dental hygiene, acute and chronic infections, accidents, and mentally abnormal children—all receive due consideration. Practical preventive measures are set forth in some detail.

The welfare of the child from its second year to its admission to school is not yet as a general rule organized to the same extent as that of the infant and of the school child. Even in those countries which have done most towards improving the health of children as a whole, the preschool age is still neglected, not so much because the importance of supervision at this age has escaped the attention of public health workers, but because of the difficulties, both theoretical and practical, which the protection of children of this age presents. The problems encountered in the campaign against morbidity and mortality during the preschool age are very different from those to be solved in infant welfare. Many, indeed, have not yet been solved from the scientific point of view, for example, the

prophylaxis of whooping cough, poliomyelitis, etc. Again, it is more difficult in practice to remain in touch with children of this age than with those in their first year; and the great majority still escape the attention of the health officer.

To undertake the effective protection of children of preschool age, the rate of morbidity and mortality for each year should first of all be established, with the help of reliable statistics, and the relative importance of the different causes of disease and death should be studied. The available statistics are largely inadequate and give no exact idea of the state of health during this period. The morbidity is only known in the case of the few infectious diseases which have to be notified, and even these notifications do not appear to be made in the same way in all countries. We are therefore compelled to use mortality statistics, which necessarily only give an imperfect idea of the condition of children's health.

The Final Report of the Departmental Committee on Maternal Mortality and Morbidity\* of the Ministry of Health of England has appeared recently. It measures up fully to the high standards already set by the Ministry of Health and reflects great credit upon Sir George Newman, the Medical Officer of Health, and his distinguished confreres, who have brought their serious investigations to practical conclusions. The report is a model of clear-cut investigation and is presented in a form which is readily understood.

The main divisions of the report deal with methods of investigation, causes of maternal mortality, consideration of an adequate maternity service, statistical summaries, puerperal sepsis, and maternal morbidity. An instructive

chapter is given to the maternity services of the Netherlands, Denmark, and Sweden, and another to the high maternal mortality in certain districts of England and Wales.

The underlying causes of puerperal deaths of 5,800 women have been carefully analyzed. The committee found that

. . . the causes of death in these cases are of varied nature—clinical and social, administrative and economic—and are closely related one to the other. Thus, clinical errors are contributed to by economic conditions, and administrative measures are rendered nugatory by reason of ingrained social customs. A complete knowledge of all the circumstances in any case of maternal death is therefore necessary before apportioning blame to any individual or institution. We are, however, convinced that the primary essential for the reduction of a high maternal mortality is sound midwifery, before, during and after childbirth, and this does not chiefly depend upon administrative arrangements or the expenditure of public money. . . .

False hopes would be raised if it were suggested that all maternal deaths are preventable. Changes in social life necessary to raise the standard of health and physical development of the women of the nation can come only with time; great advances in medical knowledge must be made before many of the risks of childbirth can be eliminated; even then the factor of human fallibility will remain.

Nevertheless, we are confirmed in the opinion expressed in our Interim Report that at least half the deaths which have come under review could have been prevented had due forethought been exercised by the expectant mother and her attendant, a reasonable degree of skill been brought to bear upon the management of the case, and adequate facilities for treatment been provided and utilized.

This report should be read by every health officer, nurse, social worker, and especially by every obstetrician.

# PUBLIC HEALTH NURSING\*

**Institutes for Public Health Nurses**—The rural nurse working alone is in great need of special institutes like those on social hygiene, mental hygiene, tuberculosis and the like, such as are given by some of the staff of the National Organization for Public Health Nursing. This nurse is a busy person and is constantly carrying on a planned program. At night she is too tired to read or study much. She needs a constant reminder that she must keep up with the latest methods of procedure in her job.

Oftentimes the nurse working alone cannot take time off to go to summer school or far off conventions. Too often, too, the problems that are worrying her are never mentioned in the professional magazines she reads. She would often be glad to take up a certain line of study if there were only reference books available.

Institutes are within the reach of every nurse because they require so little time for study at so small a cost. Given by well informed, sympathetic people who can draw out the nurses in discussion and answer their questions, they are invaluable.

After attending Violet Hodgson's institute for public health nurses on tuberculosis one nurse writes:

I have been able more intelligently to help and assist those people who were trying to carry on a program, I knew what they were striving to do, I knew what to tell the patient, how to approach the patient with conclusions that were truthful, I knew better how to approach the doctors in charge, I knew better how to understand the danger of contacts, I knew the methods used in sanitariums for treatment and I could intelligently discuss

them with the family when letters arrived from the patient about his treatment. I knew better how to stand by the family, advising and encouraging them to send letters of cheer to the patient. I knew and felt the attitude of the patient when he should arrive home and have to adjust himself to that let-down feeling. All this I found in the institute.—

Anne C. Rivers, *How Much We Need Institutes, Trained Nurse & Hosp. Rev.*, 175, 176 (Aug.), 1932.

**In a Nutshell**—The public has never scrutinized health department budgets as carefully as now. This means that some of the obsolete and outworn methods of procedure will have to go. There will have to be "more head work in health work" from now on.

Three questions the health officer and even the public health nurse should be able to answer about their communities are:

1. What is the crude death rate?
2. What is the infant mortality rate?
3. What is the typhoid fever death rate?

Physicians and public health nurses have spent too much time examining or inspecting school children and finding defects. The important thing is to get the defects corrected. More responsibility can be put on the teacher in school health work. Public health workers need to spend more time working with preschool children.

Public health officers and nurses need to bend their efforts to get *every individual under medical supervision*. Health work in the future will concern itself more with the prevention of heart trouble, diabetes, cancer and the like. To get at these we need to keep hammering away at periodical physical examinations.—C. E. Waller, M.D., *Some Needs in Our Public Health Program of*

\* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

Today. Notes from address delivered at the 1932 Annual Conference of Indiana State Health Officers.

**The Nurse and the Public Library**  
—The burden of much of the need for general health information in a community falls upon the public health nurse. Her contact with the people who are most in need of reliable information about proper living, proper nutrition, and the rudiments of the care of the sick is direct. She knows the need and her duty is to bring her people into contact with some reliable source of information. The spoken word is limited in its use. "The public library is the broadest of teachers—one may say the only free teacher."

What the public health worker may expect of her public library depends upon whether she takes the librarian into her confidence. Adequate and effective library collections on technical matters grow slowly; they are never ready made. The nurse and the librarian together should plan the public health collection for the community. With so much fine free health literature now available it is not difficult for the library to supply at little expense a good collection of pamphlets and leaflets to supplement books.

The Newark (N. J.) Public Library has the following to offer in the field of health education:

1. Professional books for nurses and health executives
2. Books for teachers giving methods of health education
3. Books for adults wishing information on nutrition, health habits, child care, and care of invalids; leaflets, documents and

- valuable clippings on all of these subjects
4. Books interesting to children, aiming to foster good health habits; health songs, poems, plays and stories
5. Posters and pictures from every possible source which are lent to schools, organizations and individuals to be displayed in all kinds of places

The health worker in an isolated rural field without library facilities near at hand may establish a small collection of documents or inexpensive leaflets to lend to her people. Or she can put them in touch with state or county library commissions. Sometimes book trucks bring collections to rural homes.

The nurse can create a demand for the type of book that will educate her public in health matters. She can recommend and advise in the selection of books which she thinks will meet the demand she has created.—Marie Louise Brush, *The Public Library, Pub. Health Nurs.*, XXIV, 9:468-9 (Sept.), 1932.

**Two Services Combined in the American National Red Cross**—In the twentieth anniversary year of both the Public Health Nursing Service and the Home Hygiene and Care of the Sick Service of the American National Red Cross, on July 1, the two services were combined into one, with I. Malinde Havey, R.N., as director. The merger consolidates the national direction of the two most important chapter activities of the American Red Cross, and the approach to both through field service, correspondence and reports will be simplified.—Public Health Nursing and Home Hygiene Combined in One Service, *Red Cross Courier*, XII, 2:48 (Aug.), 1932.

# EDUCATION AND PUBLICITY\*

**An Explanation—With Regrets—**Too many national and state meeting programs under way in September, plus emergency work in the fall money raising campaigns for health and welfare agencies, left no time for the preparation of copy for this issue of the JOURNAL—E. G. R.

**"The Newspaper as a Social Agency"**—An address, under this title, was a highlight on the program of the National Conference of Social Work at Philadelphia in June. Delivered by Sevellon Brown, of the *Providence Journal*, it presented a stimulating philosophy for the newspaper and for the social agency as seen by a newspaper man and good citizen. Believing that it should be read by all who seek the cooperation of the newspapers in spreading health and other welfare ideas, it has been published by the Social Work Publicity Council, 130 East 22d St., New York. 15 cents a copy.

Said Mr. Brown:

What appeals to me as a newspaper man, in facing you as social welfare workers, is that together we have loyalties to institutions so strikingly American.

At a recent meeting of community fund workers in my New England home a visitor, recently returned from Europe, remarked that the spectacle there before him of 700 private citizens enrolled as canvassers, reporting gifts running into the hundred of thousands of dollars subscribed voluntarily year after year by private citizens to improve the social conditions and health of less fortunate individuals, could not be found in any country of the world outside the United States. It is true that social welfare work has been very highly developed under State auspices in Europe, but its voluntary and individualistic character with us is singularly American.

So it is with the institution of the American newspaper. In many respects it has been developed in step with the press of other countries, but the commercial advertising basis upon which it rests in this country, and in which lies locked the secret of its character—its impulses to good and evil, its incomparable independence and impartiality in the vital function of disseminating news, its undeniable demagoguery and tendency to sensationalism, is decidedly idiosyncratic and peculiarly American.

Of course Mr. Brown should have included Canada in his second paragraph above.

**"Behind the Front Lines"**—This is the general title of a series of mimeographed bulletins issued by the Association of Community Chests and Councils, Graybar Bldg., New York.

They are intended for use in the local chest money raising campaigns this fall and winter. They include facts and figures, incidents and statements collected from many sources.

The series of 13 bulletins includes the following on health topics: Public Health Nursing, Tuberculosis, Hospitals, Nutrition, Mental Hygiene, Social Hygiene, and Child Health. They have gone to the chests, and some of the nationals have sent their special bulletins to their locals.

Single copies, 10 cents; the whole series, \$1.00.

**Syndicated Health Columns**—*"Editor and Publisher Ninth Annual Directory of Features"* lists the following: "Dr. Evans Health Column," by Dr. Evans; "Food and Health," by Dr. Shirley Wynne; "Health," by Dr. Morris Fishbein; "Health and Beauty," by Dr. Sophia Brunson; "Health Column," by Dr. Iago Galdston;

\* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evert G. Routzahn, 130 East 22d St., New York, N. Y.

"Health, Heart and Home Page," by International Features Service; "Here's to Your Health," by Dr. Frank McCoy; "How to Keep Well," by Dr. W. A. Evans; "How's Your Health," by Dr. Iago Galdston; "Personal Health Service," by Dr. William Brady; "Pure Food Articles," by Dr. Royal S. Copeland; "Secrets of Health and Success," by Dr. Louis E. Bisch; "Your Child's Health," by Dr. Michael Shuman; "Your Health," by Dr. Logan Clendenin; "Your Health," by Dr. Royal S. Copeland.

Then there are such "features" as: "Your Weight and Your Height" and "That Body of Yours," by Dr. James W. Barton; "How to Reduce Without Dieting"; "How I Keep My Figure"; "How I Keep Fit"; quite a group on parents, mothers, babies and children; groups covering food and home economics—most of which deal more or less with health.

**When Advertising Is Health Education**—In "The Judd Family," the Cleanliness Institute, 45 East 17th St., New York, has dramatized, in the form of historical fiction, two centuries of soap making in New England. Three episodes, selected at intervals of a century in the life of one family, point steps in the growth of progressive attitudes and daily practices of living with regard to cleanliness and sanitation. The focus is on the use of soap and the material has been primarily selected for the purpose of increasing interest in soap.

Teachers of upper elementary grades,

who are seeking supplementary material on cleanliness, will find this story of soap making, with the accompanying bits of picturesque period information, definitely useful.—By a specialist in school health education. Copy of the pamphlet free to any health worker.

**Health Division of National Conference of Social Work**—The officers and newly elected members of the executive committee are nearly all concerned with health education:

*Chairman*—Albert H. Jewell, Kansas City, Mo.; *Vice-Chairman*—Virginia R. Wing, Cleveland; *Secretary*—Alice M. Hill, New York; *Members*—T. J. Edmonds, Des Moines; Howard W. Green, Cleveland; Bleecker Marquette, Cincinnati; Elba L. Morse, Marquette, Mich.; John Sundwall, Ann Arbor; Katharine Tucker, New York.

#### CUTTING COSTS

The whole range of department or association activities might well be checked by the full page of suggestions under "Short-Cuts and Savings," by Elwood Street. *Survey*, 112 East 19th St., New York. Feb. 15, 1932. 30 cents. Two paragraphs which touch interpretation:

Are you getting out a printed bulletin which might be done on the mimeograph? Are you getting out voluminous mail advertising which by judicious editing might be reduced in volume and cost and increased in readability? Are you getting out weekly bulletins which might be sent out bi-weekly?

Are you planning far enough ahead in your work so that all details are cared for as they come up and the cost of last minute activities and hasty plans which have to be changed is eliminated?

## BOOKS AND REPORTS

**Psychology and Psychiatry in Pediatrics: The Problem.** *Report of the Subcommittee on Psychology and Psychiatry of the White House Conference on Child Health and Protection*—Bronson Crothers, M.D., Chairman. New York: Century, 1932. 146 pp. Price, \$1.50.

Unless the physician interests himself in child psychology, someone else will, is the thesis with which the report of the committee opens, and to which it clings through 43 pages of the book. "Psychiatry and psychology have opened a fascinating field of study involving the personality of the child," it is stated, and inasmuch as "at present the medical profession is regarded by most people as the natural source of advice," it is prophesied that "a practitioner of medicine who ignores the personality of the children under his care will find his position as a family adviser in definite danger."

It is admitted that the physician may have difficulty in sorting the grain from the chaff of experimentation, fact, differing beliefs, and vague ideas presented by the many works on psychology: however, "we are confident that among them are indispensable tools for medical men." It is suggested that not enough training, actually dealing with psychology, is given in medical schools. Suggestions for improving the quality of service rendered by physicians are offered on pages 30 to 32.

The differing attitudes of the psychologist, psychiatrist, and physician are discussed. The valuable services of the psychologist and psychiatrist are recognized, but it is believed that what they offer should be linked with medical training. "Obviously, it seems to us, doctors can acquire relevant psychologi-

cal and educational attitudes and techniques more safely than psychologists and teachers can acquire adequate medical assets. Adequate medical care of the child cannot be given without intelligent attention to any intellectual and emotional difficulties which may be present."

Pages 44 to 60 are taken up with discussions of the report by psychiatrists, psychologists, pediatricians, mental hygienists, and others interested in its subject matter. Their comments add to the interest and value of the book. The greater part of the appendix presents information regarding the manner in which data for the report was secured, and the manner in which typical groups such as the Merrill-Palmer School, the Child Guidance Institute, and the Essex County Juvenile Clinic of New Jersey are operated.

The Psychiatric Social Worker's viewpoint, as expressed in reply to the questionnaires used by the committee, is presented.

The book is interesting reading for either professionals or laymen.

STELLA RANDOLPH

**Directory of Clinics and Health Stations** (*Reprinted from Directory of Social Agencies, New York, 1932, pp. 433-661*). Published by the Charity Organization Society in co-operation with the Welfare Council. Reprints from New York Tuberculosis and Health Association, New York, N. Y. Price, \$.40.

This handy little volume makes available an up-to-date list of clinics and health stations in New York City. There are four divisions to the book—baby health stations, clinics, mental hygiene, and pre-school and nutrition

clinics. The name of the clinic is listed, together with the address, telephone number, the name of the director, clinic hours, and fee, if any. Under the section devoted to this subject, clinics are listed alphabetically by types of service rendered. The arrangement of clinics by boroughs adds to the usability of the directory. A list of hospitals and clinics, with telephone numbers, appears in the front of the book, and there is also a reference index.

A table showing the distribution of clinics and health stations by boroughs is an interesting feature of the book. Of the 1,751 in New York City, 1,024 are in Manhattan, 178 in the Bronx, 412 in Brooklyn, 93 in Queens, and 44 in Richmond.

ALMA W. FRAAS

**Milk Production and Control, A Publication of The White House Conference. *Report of the Committee on Milk Production and Control, H. A. Whittaker, Chairman. New York: Century, 1932. 392 pp. Price, \$3.00.***

This volume should be one of the most correct and interesting of the series to which it belongs. It is written by four sub-committees, each of which had a Board of Advisers. It contains a great deal of useful material, though it shows some of the unevenness which might be expected from the number of authors concerned. It ends with two appendices, one on Safe Milk for the Farm Family and the other on Research in Progress on Nutritional Aspects of Milk.

The most disappointing section is that on Diseases Transmitted Through Milk. Judging from the references most of the alleged facts are taken from a publication of the White House Conference in 1931, *Communicable Disease Control*.

Two pages and a half are given to bovine tuberculosis which show a lamentable lack of knowledge of the history of this subject. Theobald Smith first

showed the difference in types of tubercle bacilli in 1896 not 1898. These differences were studied by the Royal Commission on Tuberculosis in England and the Imperial Commission in Germany. The text gives them as having been done by the British Commission and at the Gesundheitsamt in Berlin. It is hard to understand why an American publication, particularly one of this type, should wish to give credit to European rather than to American work. The laboratory of the State Live Stock Sanitary Board of Pennsylvania made its report in 1902, more than 2 years before either the Royal or the Imperial Commissions, which confirmed its findings, while the New York City board of health did not make its report until 1910.

This section gives a very old quotation from Theobald Smith, which would lead one to believe that bovine tuberculosis was transmitted to children only when large numbers of bacilli were put into the system, as in udder tuberculosis, or under "certain unknown favorable conditions." This last statement may be accepted, for the fact is that no one knows the conditions under which bovine tuberculosis is transmitted to human beings. The whole tendency of this section, as well as of the first appendix, is to belittle the danger of bovine tuberculosis to human beings, although on page 369 it is stated that in some regions one-fourth of all cases in children under 16 are of bovine origin.

This volume appeared just about the time that we had the report of the Committee on Prevention and Research of the International Crippled Children's Society, and that from the committee of sixty from the People's Health League in England, the first showing that 10 to 15 per cent of bone and joint tuberculosis was bovine in origin, and that of children 0-5, 21 per cent, and of those 5-16, 26 per cent, were bovine infection, while the English Commission

reports that 2,000 deaths and 4,000 new cases occur annually in that country from bovine infection.

The fallacy of Theobald Smith's statement concerning udder tuberculosis is shown by the official figures. In England, where cows suffer from tuberculosis up to 40 per cent only 0.2 per cent, as revealed by autopsy, have udder infection. In America where the general percentage of tuberculosis is estimated at 1.9 per cent—though it runs higher in dairy districts—post-mortem examinations of animals slaughtered on account of tuberculosis show only 0.1 per cent of udder lesions.

While the book contains much useful information, many of the references are very old and it is impossible to consider it up-to-date or an entirely reliable guide, as it should be.

MAZÛCK P. RAVENEL

**A System of Bacteriology in Relation to Medicine. Vol. VIII—**  
*By W. Bulloch, L. Colebrook, J. Cruickshank, et al. London: H. M. Stationery Office, 1931. 390 pp. Price, \$6.00.*

Volume VIII of this system covers a wide field. The chapter on fungus pathogenic to man is presented so as to stress the difference in outlook of the mycologist and the bacteriologist. No attempt is made to give a summary of the literature but rather to suggest—the author states—as to how precise knowledge can be obtained. It has therefore considerable value. The *Phycomycetes*, *Ascomycetes*, *Fungi Imperfecti* and the Ringworm group are individually thus considered.

The chapter on *Actinomycosis* and similar conditions is given under three chief divisions, the aerobic actinomyces, the anaerobic actinomyces and actinobacillosis. The chapter on the pathogenic *Leptothricæ* shows how unsuccessful the attempts to define their morphology and physiology have been,

in spite of their wide distribution. The difficulty encountered is due to the inability to use artificial culture methods with success.

The largest part of the volume is devoted to spirochetes and diseases caused by them. Excellent drawings of the various spirochetes are given. The blood spirochetes of the relapsing fever type have found in the blood of man in most parts of the world with the exception of Australia, and have been given various designations, but the author states that they all belong to one widely distributed species. In the chapter on syphilis the various diagnostic tests are well discussed.

Chapters on leptospiroses, yaws, the normal bacterial flora of man and swine erysipelas are included. Each chapter contains a short bibliography.

The treatment of the subject is very uniform, and this volume maintains the high standard set at the beginning for the series. ESTHER W. STEARN

**Habits for Safety: A Text-Book for Schools—By Gentles and Betts.**  
*Indianapolis: Bobbs-Merrill, 1932. 228 pp. Price, \$.67.*

This is an excellent text for teaching safety practices and developing safety habits. That is the primary purpose of the book and it fulfils it better than anything that has come to our attention. It is intended primarily for children 10 to 14; although adults would do well to read it. It is full of helpful suggestions and useful information.

The subject matter in the text is well chosen, and presented in a manner so it can be used in a variety of ways by teachers. It can be made a part of the general course in health and hygiene or given as a special course in safety instruction. It may be correlated with instruction in other subjects in the curriculum or the material used for working out safety projects. That feature combined with well chosen subject

matter makes the book especially valuable.

The first part of the text emphasizes the importance of developing habits for safety as a basis for successful living, and it does so without attempting to lecture to the children on the subject. A series of chapters call attention to common accidents in the home, the school, the city streets, the farm and in the workshops and suggest practices necessary to prevent such accidents. The last part of the book gives instruction in first aid procedures for the injured.

The book deserves the highest recommendations as a text for promoting safety habits and practices among children.

WILLIAM DEKLEINE

**A Textbook of Bacteriology—By Kenneth L. Burdon.** *New York: Macmillan, 1932. 108 pp. Price, \$2.75.*

This textbook of bacteriology is designed particularly for the use of nurses who have had more than the minimum amount of training acceptable in nurses training schools of non-university grade. In writing this book the author has presented the subject of bacteriology in non-technical language and has attempted to show the relationship to preventive medicine and hygiene. It appears that he has succeeded remarkably in making such a complex subject as bacteriology understandable to a group of students who do not usually have the prerequisite training in chemistry necessary to the understanding of the more fundamental aspects of bacteriology as we know it today.

This volume is distinctly different from most other textbooks of bacteriology. It has little space devoted to bacterial classification, which detracts from the general interest of the subject for many beginning students. The specific organisms concerned in infectious processes are considered from the standpoint of the regions of the body

which are infected. Along with this consideration of the organisms the author discusses the normal flora of the body. One cannot but question, even in a textbook for nurses, the author's statement that *Blastomyces hominis* is a kind of yeast. The printing and make-up of the book are excellent.

NEWELL R. ZIEGLER

**The Criticism and Improvement of Diets (*Memorandum to the Minister of Health*).** *London: H. M. Stationery Office, 1932. 14 pp. Price, \$1.10.*

This is an excellent review of nutrition by the Advisory Committee to the Ministry of Health. It may be summed up in the following conclusions:

To be satisfactory the diet must yield 3,000 calories per day per "man" and contain 37 grammes of animal protein. Women and children need proportionately less. The relations of protein, fat and carbohydrate must be satisfactory.

It must also supply mineral matter (of which calcium, phosphorus, iron and iodine are the most important elements) and vitamins A, B, C and D (of which the most likely to be lacking is D, followed by A and then C).

These are best supplied in the "protective foods," *i.e.*, milk and milk products, fish (especially fat fish and fish roes), liver, eggs, fresh fruit and fresh salad vegetables.

Only when the diet satisfies all these essentials can it be considered satisfactory. No defect in one essential can be compensated by excess in another.

MAZÏCK P. RAVENEL.

**The Principles of Animal Hygiene and Preventive Veterinary Medicine—By Leunis Van Es, V.S., M.D.** *New York: Wiley, 1932. Price, \$6.50.*

This book is written by an American author and is the first one of this nature to appear in the United States. It is a valuable addition to literature on the subject, written by a man of wide experience and education in animal hygiene and preventive veterinary medi-

cine. Such a book has long been needed and is a welcome addition to the knowledge of preventive veterinary medicine. It is the product of a combined experience, thought, and judgment rarely found in veterinary literature.

The importance of a book on preventive animal hygiene is emphasized when one considers the interrelation of human and animal diseases. Quite a number of diseases affecting the lower animals are transmissible to man, and have caused many fatalities in the human family.

The first part of the work deals in a masterful way with the principles and practical details of disease prevention as applied to the farm and farm animals; the latter part discusses the individual infectious and parasitic diseases of animals, and gives the latest essential information in regard to each that is of value in applying preventive measures.

Another thing that adds to the value of the text is that the author has selected references to each chapter for those who desire to pursue the topic in greater detail.

In this text we have usable information on important veterinary matters and Dr. Van Es is to be congratulated on his presentation of the subject.

A. J. DURANT

**Diabetes**—By *Elliott P. Joslin*. Cambridge: *Harvard University Press*, 1931. 70 pp. Price, \$1.00.

The 18th volume of "Harvard Health Talks" is written by an eminent authority. It tells us of that disease which has probably yielded to man's efforts more than any other during recent years. The author says:

To have claimed 9 years ago that a knowledge of the disease and how to control it would enable one to prevent diabetic coma would have exposed one to ridicule. Whereas all diabetic children at that period died of coma, today this complication is exceptional, and almost invariably due to ignorance or gross carelessness.

The book is divided into two parts, Individual Control, and State Control. To read one is to read the other—and both should be read by everyone, diabetic or otherwise. From the first, one gets the inspiration that possibly the individual may sometime learn to evaluate his medicaments, for the author says:

It is unfortunate that the worthlessness of quack medicines in all diseases cannot be tested as readily by the patient as in diabetes, because if this were the case the cost of medical care in the United States would be reduced by millions of dollars.

From the second we learn that public health concerns things other than infectious diseases—and that diabetes is on the increase.

C. F. ADAMS

**The Business Man and His Health**—By *Jesse Feiring Williams, M.D.* New York: *McGraw-Hill*, 1932. 175 pp. Price, \$2.00.

When, if ever, a business man sets forth on a literary pilgrimage in quest of the salubrity which most industrialists are erroneously thought to lack, he craves entertainment and inspiration as well as information. From this book, if he could be induced to read it, a business man might derive much healthful information, but he would secure from it but little, if any, amusement, recreation, or excitement. It requires more than an occasional witticism to offset continuous dullness, and this book is distressingly prosaic.

Included in it are such inevitable topics as health examinations, the functions of man, vacations, hobbies, exercise, "muscles and mussels," mental hygiene doctors, the perennial bromide—"the tired business man"—few of whom are ever actually overcome by lassitude, and a pun on the same subject—"the retired business man." None of it is calculated to overcome the inherent sales resistance of the average American mercenary, despite the fact

that most modern business men ought theoretically to have plenty of time now for reading. They require something more thrilling than this.

JAMES A. TOBEY

**Journal Southeastern Section American Water Works Association, Proceedings of Fourth Annual Meeting, Atlanta, Georgia, Vol. 2, No. 1, 1932.**

This journal publishes the papers presented at the Fourth Annual Meeting of the Southeastern Section of the American Water Works Association, held at Atlanta, Ga., March 22-24, 1932. Many papers of general interest included "Advances and Developments in Powdered Activated Carbon" by F. E. Stuart; "Our Streams and Their Flow" by E. D. Burchard; "Information on Water and Sewage Works Problems—Where It Can Be Found" by Linn H. Enslow; and "Some Trends of Municipal Sewage Disposal Practice" by Wellington Donaldson. Other papers presented were "Turbidimeters in Use at the Atlanta Filtration Plants," "Wells and the Part They Play in Our Water Supply," and "Water Works Accounting." Descriptions are given of the water softening plant at Thomasville, Ga., and of the water supply of Spartanburg, South Carolina.

VINCENT B. LAMOUREUX

**Population Characteristics by Census Tracts, Cleveland, Ohio, 1930**  
—By *Howard Whipple Green*, with a foreword by *Leonard P. Ayres*. Cleveland: The Plain Dealer Publishing Co., 1931. 236 pp. Price, \$25.00.

This volume contains a comprehensive analysis of the population of Cleveland, by census tracts and of 4 adjoining cities, according to age, sex, nativity, economic, social, and other factors. The first 72 pages are devoted to many valuable charts, graphs, maps, and general

tables with descriptive text, and illustrate how any city may, with the co-operation of the U. S. Bureau of the Census, which provided the basic data, study systematically its local problems relating to the people. The balance of the volume presents the detailed statistics by census tracts and an index map.

In bringing these exhaustive census data together, supplemented by additional material for 252 census tracts of the 5-city area, the author has rendered a most valuable service. The illustrations of various methods of applying census tract data to local problems are helpful to those who wish to study the economic, social, and health problems of a city on a district basis. As stated in the foreword, "The possibilities of the use of this material as a guide in all economic, social, and health programs are limitless, and the analysis of material is so carefully developed that even to one unacquainted with statistics, the basic facts stand out."

IRA V. HISCOCK

**Classic Descriptions of Disease. With Biographical Sketches of the Authors—By Ralph H. Major, M.D.** Springfield, Ill.: Thomas, 1932. 630 pp. Price, \$4.50.

Members of the medical profession, regardless of whatever specialty they may practise, owe a debt of gratitude to Dr. Major for this work, which represents an enormous amount of research, judgment in selection, and a great deal of work in translating articles from the languages in which they were written. There are 376 selections from original texts written by 179 authors, and 130 illustrations, many of which are unusual portraits, facsimiles of title and text pages, reproductions of apparatus and drawings, etc., all of which are excellent and full of interest.

The arrangement leads to some duplication. The selections are grouped under 10 heads, with the particular condi-

tion or disease and the authors of the papers placed under these heads. We would like to suggest some rearrangement. For example, under Infectious Diseases, sub-heading Tuberculosis, are 2 pages by Laënnec on Physical Signs of Tubercles, while under Diseases of the Digestive Tract, more than 500 pages further on in the book, we find his photograph, a brief sketch of his life, and the description of mediate auscultation, and the discovery of the stethoscope. Laënnec owes his fame more to this discovery than to any other one thing, though everyone recognizes him as a master of medicine. The quotation in this latter place concerns cirrhosis of the liver, to one type of which he gave his name, but he describes the case as "Hemorrhagic pleurisy of the left side, with ascites and organic disease of the liver," and it is found in his treatise on auscultation. One extract from his writings is also found under Diseases of the Circulatory System, and four under the head of Respiratory Diseases.

In the preface the author properly calls attention to the study of medical history urged by Sir William Osler. Another of our great teachers, Dr. Victor C. Vaughan, also insisted on the historical method of teaching. Some of our schools have introduced courses on the history of medicine, but we know of no other book which not only gives the biography of the masters of medicine, but also the selections from their writings which are most famous as well as useful. The average physician, even in cities of considerable size, does not have a library at hand which contains the originals of anything like the material here given. Everyone who has taught medicine knows that the average student is densely ignorant even of the names of those founders of medicine which should be as familiar to him as his own. Here in one volume, the author has given us the story of 179 men who have played a leading part in the

development of medical science as we know it today. He has not confined himself to men of old, but has included quite a number of those now living. It is something of a disappointment not to find the names of men like Koch, Schaudinn, Kitasato, Bordet, Wassermann, Klebs, Metchnikoff, Loeffler, and others. These have been purposely omitted because their discoveries were bacteriological, while the field of the book is chiefly clinical medicine. We miss also such names as those of Oliver Wendell Holmes and Semmelweis, though certainly the investigations on puerperal fever by these two men concern clinical medicine directly.

These are suggestions rather than criticisms. The book as a whole fills us with admiration, not only on account of its contents, but also because of the enormous amount of well considered and well directed energy which the author has shown. It is one of the most useful which has been published for a long time, and deserves a wide circulation not only among physicians in general and libraries, but also as a textbook in medical schools. The printing and make-up of the book are excellent, though there are a number of typographical errors. It is printed on very heavy paper, perhaps because of the large number of illustrations. We congratulate both the author and the publisher on this piece of work.

MAZÏCK P. RAVENEL

*Hygiene of Community, Home and School—By E. W. Steel and Ella G. White. New York: Harper, 1932. 386 pp. Price, \$2.25.*

In emphasizing health knowledge as an adjunct to good citizenship the authors present their subject matter in a new light. The book contains 23 chapters and includes numerous illustrations, charts, pictures, and diagrams. It covers the entire field of public health as it appeals to, and can be absorbed by,

the student in teachers' colleges or other colleges offering courses in this field. Public health officials will also be interested in the method of approach.

Besides chapters on milk, water, excreta disposal, plumbing, rodent control, insect control, and food protection, the book also discusses the economics of health, the activities of health departments, child and maternity hygiene, and the importance of light and ventilation with reference to health. The legal aspects of public health work are covered in a separate chapter. This new book thus provides ideal material for college health courses.

ELLA G. WHITE

**Quantitative Clinical Chemistry—**  
*Vol. I, Interpretations—By John P. Peters and Donald D. Van Slyke. Baltimore: Williams & Wilkins, 1931. 1,264 pp. Price, \$12.00.*

This volume was begun about 7 years ago. In it and the companion volume on methods the clinician and the biochemist have joined hands to produce what appears to be the most comprehensive and authoritative book on the subject in this country. The names of the collaborators need no introduction.

In their preface, the authors inform us that the collaboration is a close one; scarcely a paragraph escapes being the joint work of both men. The intention in the discussions is to treat "those substances which are of importance in clinical medicine and for the determination of which suitable methods are available."

The general plan of the book gives the physiological rôle of the substance under discussion, followed by a consideration of its significance in diagnosis and therapy. The physiological sections fill more space than the clinical application, "because the disease processes are only special examples of extreme functional disturbances," and "because so little is known of the

changes in disease of some of the substances considered."

Only occasionally is more than passing notice given to historical considerations, such as under glucose. However, full bibliographies are given at the end of each chapter which total over 4,000 references and serve as an excellent and convenient key to the literature of this important field. The book undoubtedly will stand at the head of the list of publications on this subject.

C. F. ADAMS

**Quantitative Clinical Chemistry—**  
*Vol. II, Methods—By John P. Peters and Donald D. Van Slyke. Baltimore: Williams & Wilkins, 1932. 957 pp. Price, \$10.00.*

To the laboratory man, this is the most important publication for many years. It is full of methods and procedures applicable to any laboratory, and replete with material not found in any other manual.

Fortunately for the non-chemist, Chapters I and II concern general chemical technic and special biochemical technic. These occupy 83 pages and deal not only with fundamentals but with many simple dodges and handy procedures that every laboratory worker needs.

The authors have followed the general plan of describing methods of different types for each substance, thus enabling any worker to choose according to his needs or tastes. This includes a gravimetric, a titrimetric, a colorimetric and a gasometric procedure when desirable methods for each were available with, if advisable, macro and micro forms. Each chapter is prefaced with a discussion of the principles on which the methods are based, drawn in such a way that the discussion serves as a guide to the literature.

While there is more or less grouping of procedures for the determinations of any given substance, gasometric methods for sugar, urea, etc., etc., are not

placed in the chapters concerning these substances, but are gathered into a chapter by themselves. It is interesting to note that some of the details of the gasometric methods in Chapter VII are somewhat in advance of the original descriptions.

The authors have added an appendix for methods not strictly within the scope of quantitative analyses as here presented, though used in clinical laboratories. They include such procedures as concern renal and hepatic function tests, bile pigments in blood, plasma, etc. As in the companion volume, each chapter is concluded by a useful bibliography. The volume ends with an author index and a subject index.

One dislikes to call attention to insignificant typographical errors in such a good book, but the publishers' "Sans Tache" should be better guarded. For instance, pages 9, 61, 217, 508, and 571 have errors and others could be cited. Upon the whole, nothing on methods has come off the press in recent years comparable to this volume.

C. F. ADAMS

Proceedings of the Ninth Annual Short School, Texas Public Health Association, November 9-14, 1931.

The Texas Association of Sanitarians, now the Texas Public Health Associa-

tion, affiliated with the American Public Health Association, held the largest and most successful Short School of its career at Houston, Tex., November 9-14, 1931. The Proceedings are divided into 4 sections, the first including a summary and registration list, and the second a group of papers relating to medical and administrative public health, including the subjects of tuberculosis prevention, diphtheria protection, vital statistics, health work of the Shriners, significance of the U. S. Chamber of Commerce health contests, school superintendents and health work, new physical education law and health education, and the need of a new sanitary code for Texas.

Papers presented in the third section on nursing and sanitation include itinerant nurse services, science of sanitation, sanitation in industry, military sanitation, prison sanitation, a malaria control program for Texas, importance of a national unified milk sanitation program, the new Arizona dairy law, and oyster sanitation. The fourth and last section is devoted to papers relating to the laboratory, including a description of the State Hygienic Laboratory, bacterial counts of milk methods, practices causing errors in the Babcock test, thermophilic bacteria, and operation of the Texas standard milk ordinance program.

VINCENT B. LAMOUREUX

## A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Weather and Pneumococci—Pneumococcus incidence in normal throats was highest in inclement weather. In some cases, there was an association between respiratory infections and Group IV pneumococci. Note the length of the title.

BROWN, M. H. and ANDERSON, E. A further Bacteriological Study of the Bacterial Flora of the Throat of Normal Persons and Persons

with Minor Respiratory Infections with Especial Reference to Pneumococcus. *J. Prev. Med.* 6, 5:407 (Sept.), 1932.

Typhus Fever—Evidence is presented establishing two manifestations of typhus; the highly communicable form is louse-borne, whereas the endemic form is transmitted from rat to man by fleas and not from man to man except

in lousy populations. Lice, ticks, mites, and other "insects" may possibly transmit the disease from rat to rat.

DYER, R. E. *et al.* Endemic Typhus Fever of the United States. J.A.M.A. 90, 10:795 (Sept. 3), 1932.

**Is Raw Milk More Nutritious Than Pasteurized?**—"The growth-promoting capacity of heated milk plus supplementary diet received by the average American child of 10 months to 6 years is not measurably less than the growth promoting capacity of raw milk plus the (same) supplementary diet." This exact and somewhat stilted statement summarizes a statistical study of growing youngsters in answer to the raw milk propaganda. However, the same propaganda will rise superior to the mere enumeration of statistics no matter how exact may be the control.

FRANK, L. C. *et al.* Do Children Who Drink Raw Milk Thrive Better Than Children Who Drink Heated Milk? Pub. Health Rep. 47, 39:1951 (Sept.), 1932.

**Seasons for Colds**—Statistical evidence of the conclusions based upon common observation that colds are generally less prevalent from April through August, with a "low" late in July or early in August, and high in prevalence from September to March inclusive.

FROST, W. H. and GOVER, M. The Incidence and Time Distribution of Common Colds in Several Groups Kept Under Continuous Observation. Pub. Health. Rep. 47, 36:1815 (Sept. 2), 1932.

**Drill Dust Removal**—Dust removed by exhaust from rock drills not only protects the operator but improves the speed of the drill at small cost.

HATCH, T. *et al.* Control of the Silicosis Hazard in the Hard Rock Industries. J. Indust. Hyg. 14, 7:246 (Sept.), 1932.

**Tonsillectomy and Health**—"Excellent end-results in selected cases have been statistically over-weighted by in-different end-results in cases in which

the operation has been performed without sufficient indications as a more or less routine prophylactic ritual. In our opinion, a large proportion of the tonsillectomies now done on children are unnecessary, entail some risk, and give little or no return." Thus concludes a British study.

GLOVER, J. A. and WILSON, J. The End-Results of the Tonsil and Adenoid Operation in Childhood and Adolescence. Brit. M. J. 3740:506 (Sept. 10), 1932.

**Staphylococcus Dissociation**—Demonstrating a filtrable form of *S. aureus*, probably a cyclo-stage, during which the organism is avirulent, the authors offer the suggestion that this may explain how the organism lurks in the body without manifestations only to appear in lesions later when virulence returns.

HOFFSTADT, R. E. and YOUNG, G. P. *Staphylococcus Aureus*: Dissociation and Its Relation to Infection and Immunity. J. Infect. Dis. 51, 2:216 (Sept.-Oct.), 1932.

**Compulsory Smallpox Vaccination Heresy**—British health officials in this symposium frankly question the wisdom of compulsory vaccination in Great Britain in the absence of the severe type of smallpox.

LEDINGHAM, J. C. G. *et al.* Vaccination. J. Roy. San. Inst. 53, 3:134 (Sept.), 1932.

**British Maternal Mortality**—Frank, though not new, is this discussion of the causes of maternal and infant deaths in England. The important factors of sepsis, abortion and illegitimacy are given the consideration they deserve.

McILROY, L. The Prevention of Maternal and Infant Mortality. J. State Med. 40, 9:497 (Sept.), 1932.

**Settlements for the Tuberculous**—Papworth Village is cited as evidence of the value of and need for a system of tuberculosis settlements throughout Great Britain. It would seem that the

same conditions hold true this side of the Atlantic as well.

VARRIER-JONES, P. Tuberculosis Settlements. *J. State Med.* 40, 9:536 (Sept.), 1932.

### Experiments With Poliomyelitis

—In a series of three papers, the author presents evidence of a toxic factor in the stools of poliomyelitis patients which, when injected into guinea pigs, causes conditions strikingly like those found in human patients. This virus

can be neutralized by previous injection of convalescent serum.

TOOMEY, J. A. Demonstration of a Toxic Factor in the Stools and Urines of Poliomyelitis Patients. *J. Prev. Med.* 6, 5:379 (Sept.), 1932.

Adult Hygiene—Heart disease, pneumonia, tuberculosis, and student and industrial health are discussed in a stimulating Canadian symposium.

ONILE, J. A. *et al.* Adult Health. *Canad. Pub. Health J.* 23, 9:403 (Sept.), 1932.

## NEWS FROM THE FIELD

*It will be appreciated if readers will send to this department such items of news interest concerning public health activities as they consider suitable.*

### REORGANIZATION OF ITALY'S NATIONAL BUREAU OF MATERNAL AND CHILD WELFARE

THE National Bureau of Maternal and Child Welfare of Italy has recently been reorganized on the basis of 5 years' experience. In the decree on reorganization it was pointed out that the work of the bureau is not to provide relief, but to help the needy through moral and material means to become self-supporting and capable of living in society.

The new plan aims to provide a uniform well coördinated method of maternal and child welfare work instead of the present disorganized and diversified system, to establish maternal and child welfare agencies even in the remote rural districts, and to introduce trained and paid welfare workers instead of the volunteers by which most of the work of the bureau has been done so far.

The provincial branches, heretofore each in charge of a council and committee of volunteers, will now be conducted by paid directors, experienced in maternal and child welfare work and in administrative matters. The technical specialized organ of the provincial branch, heretofore lacking, will be the office of social work (social secretariat), which will organize new welfare agencies and will supervise and coördinate all the work in the province. The actual work of the provincial branch will be done by new agencies called "centers of assistance to mothers and children." Each province will be divided into urban and rural districts, in each of which such a

center will be established. The work of the center will be carried out mainly by a social-service office and a clinic for mothers and children. The social service office will do case work.

The clinic will not be for the purpose of treatment, but for the purpose of teaching the mother proper care of herself and her child, with a view to prevention of illness. In those rural districts where it would not be feasible to organize stationary centers, their work will be done by traveling centers. To each clinic there will be attached a day nursery for children between the ages of 3 months and 3 years and a dining room for mothers. Day nurseries for children 3 to 6 years of age must be established in children's institutions which are already in existence.

The regulations also provide for the employment of social workers both in urban and rural localities, and for the establishment without delay of courses for the training of officials and subordinate employees. According to the latest information, such courses have been established already in two cities.

The bureau is maintained by appropriations from the national treasury and by private contributions.—*Maternità ed Infanzia*, Rome, May and June, 1932; *Rassegna della Previdenza Sociale*, Rome, June, 1932.

### IIADASSAH

THE eighteenth annual meeting of the Hadassah National Women's Zionists organization was held in New York September 19-20. Dr. Haim Yassky, Director of Hadassah medical activities in Palestine, described the work being done there. Since 1925, largely through its efforts, infant mor-

tality has been reduced from 53.5 per 1,000 to 22.1 in 1931.

Dr. Nathan Ratnoff, chairman of the American Jewish Physicians' Committee, announced this committee's cooperation with Hadassah in the establishment of a medical center in connection with the Hebrew University of Palestine.

Prof. C.-E. A. Winslow, of Yale University, was one of the speakers.

#### NURSING CALENDAR FOR 1933

THE National League of Nursing Education is presenting a hanging calendar of quotations which will make an appropriate gift. The title is "Quo Vadis?" and the cover page is from a painting by H. Willard Ortlip, who painted the cover for the Florence Nightingale calendar. The price of the calendar will be \$1.00 per single copy and \$.75 per copy for quantities of 50 or more—National League of Nursing Education, 450 Seventh Avenue, New York, N. Y.

#### HOSPITAL INSURANCE IN DALLAS

THERE are two hospital-insurance plans now operating successfully in Dallas, Tex., where the Baylor and Methodist Hospitals have separate contracts with several thousand employed persons.

For the payment of \$.50 a month, the hospital agrees to provide, without extra charge, hospital service when needed for a period not to exceed 21 days during a 12-month interval. After 21 days the beneficiary is given a one-third discount on regular and special hospital services required during an illness.

Contagious, tuberculosis, and mental cases are not included in the benefits after they have been diagnosed as such. Obstetrical cases are granted 50 per cent discount on hospital services.

The financial experiences of the Baylor and Methodist Hospitals indicate that the plans in effect are actuarially sound. In one hospital the average receipts per patient-day of care were \$6.60, in the other \$7.60. It was found

that approximately 10 per cent of the members used the service a year, and that the average length of stay was approximately 9 days. Both of the Dallas hospitals are convinced that the total revenue from these members is greater than would have been paid by the individual patients on a private-fee basis for hospital service.

C. Rufus Rorem, of the staff of the Committee on the Costs of Medical Care in his book, *The Crisis in Hospital Finance*, states that voluntary sickness insurance on a group basis is steadily growing in favor.

#### IOWA ASSOCIATION MEETING

THE Iowa Public Health Association held its annual meeting in Des Moines October 6-7. Among the topics considered were: "The Veterinarian's Interest in Public Health," "The Building and Maintenance of Swimming Pools," and "Energy Cost of Work in Normal Children."

#### REPORTING OF THE BIRTHS OF DEFORMED CHILDREN IN ITALY

A LAW of May 16, 1932, requires every physician or midwife attending the birth of a deformed child to report the fact to the local mayor or health officer.

According to the same law any physician who in treating a patient notices symptoms that are causing or may cause in the future inability, even if partial, to work for a living must report the fact to the previously mentioned authorities. Fines are prescribed for violations.—*Gazetta Ufficiale*, Rome, June 11, 1932.

#### PERSONALS

DR. FRANK M. LAWSON, of Willows, has been appointed Health Officer of Glenn County, Calif., succeeding the late Dr. Samuel Iglick. Dr. Thomas H. Brown succeeds Dr. Iglick as Health Officer of Orland, Calif.

DR. DAVID M. KINDOPP replaces the late Dr. Charles J. Durand as Health Officer of Colfax, Calif. Dr. Kindopp is also Health Officer of Placer County.

DR. LOUIS L. ROBINSON has been appointed Health Officer of the recently incorporated city of Fairfax, Calif.

DR. EUGENE N. NESBITT, of Grand Rapids, Mich., has been appointed Director of City Welfare. He will continue his duties as superintendent of the city tuberculosis hospital.

DR. OLLIE M. GOODLOE, F.A.P.H.A., of Louisville, Ky., has been appointed to succeed Dr. Sam R. Page as Health Officer of Breathitt County, Ky.

DR. GRADIE R. ROUNDTREE, of Horse Cave, is the New Health Officer of Adair County, Ky.

DR. CHARLES FRED BLANKENSHIP, of Hawesville, has been appointed Health Officer of Hancock County, Ky.

DR. CARL N. GAMBILL, member A.P.H.A., of Salyersville, succeeds Dr. Miriam Marting as Health Officer of Greenup County, Ky. Dr. Marting recently resigned.

DR. ARTHUR J. REVELL, of Arma, became Health Officer of Cherokee County, Kans., on September 1, succeeding Dr. Clarence R. Hepler, who has accepted a similar position in Sedgwick County, Kans.

DR. HARRY C. HUMMELL has been announced as the new Deputy Health Officer of Rochester, N. Y., to succeed Dr. Arthur M. Johnson, who recently became Health Officer on the retirement of Dr. George W. Goler.

DR. C. L. OUTLAND, member A.P.H.A., who has served as Chief Medical Inspector in charge of contagious

diseases for the Richmond City Bureau of Health for the past 6 years, has been appointed Medical Director of the Public Schools of Richmond, Va., succeeding Dr. N. T. Ennett who resigned.

MAGNUS W. ALEXANDER, member A.P.H.A., died September 10, at the age of 62. He was formerly connected with the General Electric Company, held the post of chairman of the Massachusetts Commission on Old Age Annuities and Pensions, and was a member of the Commission on Compensation for Industrial Accidents in Massachusetts. He was the author of the book *Safety in the Foundry*, as well as many articles on economic subjects. Mr. Alexander headed the National Industrial Conference Board since its organization in 1916.

## CONFERENCES

November 4, New York State Association of Public Health Laboratories, Albany, N. Y.

November 6-11, Fifteenth Annual Convention, American Dietetic Association, New York, N. Y.

November 11-12, Third Biennial Conference of the National Council of Parent Education, French Lick Springs, French Lick, Ind.

November 14-16, Southern Branch A. P. H. A., Birmingham, Ala.

November 14-16, Southern Medical Association, Birmingham, Ala.

November 14-16, National Malaria Commission, Birmingham, Ala.

November 14-18, Tenth Annual Short School, Texas Public Health Association, Dallas, Tex.

## American Water Works Association

FOUNDED 1881

An organization conducted to enlarge our knowledge of the quality, provision, purification and distribution of water for public and private purposes, and to improve the management of water works.

Both individual opinions and experiences and the investigations of special committees are reported in its monthly Journal. Persons interested in water supply can obtain full information about the Association from the Secretary's Office, at

29 West 39th St., New York

## The Rôle of Activated Milk in the Anti-Rickets Campaign\*

ALFRED F. HESS, M.D.

*New York, N. Y.*

IN endeavors to protect the community from disease our usual concern is to have at our command a specific agent or some preventive method which is effective. In regard to rickets quite the contrary holds true. In this disorder we are burdened with such a multiplicity of preventive agents that we find ourselves at a loss to decide which one to select. We have at our disposal direct irradiation with ultra-violet rays, cod liver oil or its concentrates, viosterol, activated milk, and still others. This is by far the greatest array of specifics which can be marshalled against any disease. In the course of the past few years, however, the problem has become simplified for it is increasingly evident that, from a communal standpoint, the best method of preventing rickets involves the use of some form of antirachitic milk and, furthermore, that we must draw a distinction between measures which are most suitable for the prevention and those most suitable for the cure of rickets. As has been emphasized elsewhere, there are two reasons why an activated milk should be singled out for prophylactic use; first and mainly because it provides a therapeutic measure which is automatic, in that the specific agent is embodied in the food which is essential for the nutrition of the infant. In addition, milk has the distinction and advantage of being the food which contains calcium and phosphorus in highest degree.

It is now over 7 years since I reported experiments showing that

---

\* Read as a part of the Symposium on Milks of Special Antirachitic Value before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting at Washington, D. C., October 26, 1932. Other papers from the Symposium will be published later. The Report of the Committee on Milk and Dairy Products, dealing with the administrative aspect of the same subject, will appear in the Year Book.

milk can be activated by means of exposure to ultra-violet energy.<sup>1</sup> However, although milk of this kind has been used on a considerable scale in a few cities in Europe, notably Frankfurt, Germany, it has not been used commercially in this country, except in the form of irradiated dry milk. As you know, instead of elaborating an antirachitic milk by means of direct irradiation this end may be accomplished by means of feeding cows activated yeast. Furthermore, milk may be given antirachitic properties by mixing irradiated ergosterol with it, as has recently been shown by Laquer,<sup>2</sup> or by adding a concentrate of cod liver oil. However, these two methods, whatever advantages or disadvantages they may prove to entail, cannot be considered at the present time as neither of these types of milk has been subjected to extensive clinical test, which after all is imperative in all questions involving human nutrition.

As reported a year or more ago, the milk of cows which are receiving large quantities of irradiated yeast develops high antirachitic potency and may be recommended to protect infants from rickets.<sup>3</sup> This measure is being used to an increasing extent on numerous farms, mostly of the certified variety, in various sections of the United States. It is a procedure that is applicable especially to the certified farm, where the ration of the cows can be thoroughly controlled and one can be certain that a potent yeast is fed in adequate amount, and more particularly, where frequent biologic assays of the milk can be carried out. It would seem, however, that it is hardly applicable for the general supply of large communities, especially for great cities which require many thousands of farms to meet their demands. For this purpose irradiation has an inherent advantage, in that the milk can be activated at a central station, perhaps at the same time that it is subjected to pasteurization.

I shall not enter into a consideration of the technic of activation as this aspect has been considered recently in several communications.<sup>4</sup> It is sufficient to say that milk can be rendered highly antirachitic by subjection, for a period of merely 16 seconds, to the radiations of certain carbon arc rays, and that in the course of this process it does not develop any disagreeable taste or odor nor is it deprived of its essential vitamins. If we would obtain a product which is reliable and constant, it is necessary, as emphasized in an investigation with Supplee and Dorcas, to carry out the irradiation under fully controlled conditions.<sup>5</sup>

In a clinical test carried out during two winters in baby health clinics of the Department of Health in New York, it was established unequivocally that such irradiated milk is able to prevent rickets

almost without exception. Indeed, it prevented the development of this disorder in negro infants who are exceptionally susceptible. It should be added that the majority of these infants were under 6 months of age and received three-quarters rather than an entire quart of milk daily. Biologic assays of this milk showed that it did not vary to a great extent in vitamin D content. In general it may be stated that the variation of vitamin concentration in foods, not only of the antirachitic factor, but of other vitamins as well, has been stressed far too greatly. It should be remembered that nature supplies us with vitamins quite irregularly and that her quota is by no means rigid. For example, nothing could be more variable than our daily quota of the antirachitic factor. This varies in amount according to exposure to sunlight, to whether the day is clear or cloudy, whether we are out of doors much or little or expose our bodies to a greater or less extent and, particularly, according to season and to whether we live in the North or in the sunny South.

There is another point which I wish to emphasize—the clinical distinction which has been found to hold true in regard to the potency of various antirachitic agents. It is the established custom to refer to an antirachitic agent such as viosterol, cod liver oil, or irradiated milk, as possessing a certain number of antirachitic units per c.c. or per quart. Indeed, it has been accepted that the potency of one preparation may be expressed in terms of another, for example, that the strength of viosterol may be stated in terms of cod liver oil. In 1930, we reported clinical observations which showed that this assumption, based on assays on rats, does not accord with clinical experience, in that much more viosterol was needed to protect infants than should be expected or required, as judged by bioassays of the two antirachitic agents.<sup>6</sup> In 1931 a similar discrepancy was pointed out in connection with a comparative clinical test of viosterol with “yeast milk” and with irradiated milk.<sup>3</sup> The preventive dose of these three antirachitic agents is approximately 24 ounces of yeast milk, 3 teaspoonfuls of cod liver oil, or 10 drops of viosterol. Translated into terms of rat units this means that 120, 200, and 800 units are required, respectively, as a daily prophylactic dose. This inequality, from the laboratory point of view, was quite unexpected. The problem was emphasized still further when it was found that 35 units of irradiated milk, as determined by the standard rat technic, sufficed to protect a large series of infants.

Clinical experiences of this kind are supported by suggestive laboratory observations which have been noted during the past few years. For example, over 2 years ago it was shown that chickens require a far

larger number of antirachitic units when this factor is supplied in the form of viosterol than as cod liver oil.<sup>7</sup> These observations have been substantiated and extended from various sources. In view of various considerations of this nature I suggested at Stockholm in 1930 that "it is possible that in addition to vitamin A, cod liver oil contains something which is of value in rickets and which is not present in irradiated ergosterol." "

Observations on cows have led to the discovery of similar discrepancies. It was found that about three times as much irradiated ergosterol as of activated yeast had to be incorporated in the daily ration in order to procure approximately 160 units of antirachitic vitamin in a quart of milk. Recently, Krauss and his colleagues reported a similar lack of uniformity, from the point of view of unitage, in the therapeutic activity of butter fat and of cod liver oil.<sup>9</sup> Without going into further detail, it would seem, as a result of these clinical and laboratory experiences, that we should not generalize in regard to the potency of the various antirachitic agents, but that we must be guided by the clinical activity which each is found to possess. Furthermore, one preparation should not be compared to another, for example, activated milk with viosterol, or viosterol with cod liver oil. It is permissible merely to draw a comparison between various preparations of the same kind, of viosterol to viosterol, of cod liver oil to cod liver oil. Such being the case, it is evident and should be clearly understood that the new "international unit" for vitamin D which allows a solution of irradiated ergosterol or of cod liver oil of known antirachitic potency to be used as "the standard of reference" does not imply that, from a clinical point of view, these two agents are equivalent.

Activated milk, in the fluid or dry form, possesses the advantage not only of providing an automatic method of preventing rickets and of supplying this essential factor in a medium rich in phosphorus and calcium, but, as has been shown, it accomplishes this end by means of an exceptionally small amount of the antirachitic factor. In view of these important advantages I do not hesitate to recommend the general use of such milk for infants and children, especially in large communities. Whether adults, whose bones are growing at a much slower rate, require a supplement of vitamin D to their dietary must be left undecided, to be answered according to the outcome of subsequent investigation. There can be little doubt, however, that the rapidly growing organism requires this factor and that, in the temperate zones, the infant and child do not receive the optimal amount from the radiations of the sun and from the meager supply in the food.

NOTE: Such experiences with antirachitic agents make one wonder whether similar discrepancies may not exist in the realm of other vitamins; for example, whether carotin exerts the same activity clinically as an equivalent number of vitamin A units of cod liver oil, butter, vegetables, etc.

---

## Prevention and Cure

" . . . A rational distinction may be drawn, and even a logical contrast set out, between medical activities primarily put into operation in the interests of the individual—or medical practice which is mainly clinical—and those principally directed to the well-being of a community; but this is very far from establishing an antithesis between prevention and cure.

When legitimate distinctions are intended they should be exactly and accurately stated, and it is time that the false contrast should not only be discouraged both in medical and in popular writings and speeches, but ended. . . ."

In this address Sir George Newman shows, with his usual charm of style and his usual abundance of illustration and example, that during the past hundred years almost all the great advances in what is called preventive medicine have been made possible and actually brought about by private practitioners, and mainly in the course of their ordinary clinical work. There have been some great sanitarians and some famous laboratory workers in this field who were laymen, but in the fascinating story of modern preventive medicine "there is nothing more significant or more illuminating than the constructive service which has been rendered by medical practitioners. It is they who have made the bricks, found the road, explored the facts, carried on the fight, and educated the people in a way of life. . . . The medical man is an individualist and he is educated by an inductive method. All unconsciously, without losing his individualism and by way of induction, he has been the builder of State medicine and has opened wide the gates of prevention." The exuberance of metaphor merely emphasizes the importance of the achievement. "In every branch of medicine and in every county of England practitioners have placed their names permanently upon a roll of fame as preventive benefactors and explorers."—Editorial, *Brit. M. J.*, July 30, 1932, pp. 209–210.

DOROTHY V. WHIPPLE, M.D., AND JOSEPH STOKES, JR., M.D.  
*Medical School, University of Pennsylvania, Philadelphia, Pa.*

THE multiplicity of antirachitic agents available at the present time has resulted naturally in efforts by both laboratory and clinical workers to determine their relative values. The biological assays of these various agents have made available data concerning their potency in units of vitamin D. But we would emphasize the fact that biological assays on animals have overshadowed the clinical data obtained upon human infants, and that the clinical value of a given antirachitic agent does not necessarily parallel its potency in terms of rat units.

Hess and Lewis<sup>1</sup> have recently pointed out the fallacy of estimating necessary human dosage of different antirachitic agents purely on the basis of rat assays. They have also shown that the greatest discrepancy arises when vitamin D fortified milk is compared with other antirachitic agents.

This study is concerned with the determination of the antirachitic potency of various types of vitamin D fortified milks; using in parallel series groups of human infants and rats. This preliminary report deals with three types of milk:

Milk irradiated with the carbon arc lamp  
Milk from cows fed irradiated yeast or "yeast milk"  
Milk from cows irradiated with the carbon arc lamp

We are especially interested in the last named product because of the lack of clinical studies of its efficacy and because of the recent

\* Read as a part of the Symposium on Milks of Special Antirachitic Value before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting at Washington, D. C., October 26, 1932. Other papers from the Symposium will be published later. The Report of the Committee on Milk and Dairy Products, dealing with the administrative aspect of the same subject, will appear in the Year Book.

development for practical purposes of the more powerful carbon arc lamps.

Previous studies of great value have been reported upon irradiated milk. Hess and Lewis,<sup>1</sup> in the study mentioned, reported the units of vitamin D in fluid milk irradiated with the carbon arc lamp, together with the prevention and treatment of rickets in human infants by means of this milk. They found that less than a quart of such milk would protect infants from rickets despite the fact that it contained "only 50 units of vitamin D as assayed by the standard rat technic." However they do not mention how much less than a quart of this milk will protect infants from rickets. Hess, Supplee,<sup>2</sup> and their coworkers had published studies upon the number of units of vitamin D in dried milk, irradiated with carbon arc lamps, previous to drying. Their results with dried milk were entirely in accord with the results of their studies upon fluid milk. Many other valuable studies have been made upon the direct irradiation of milk, among which those of Watson,<sup>3</sup> and Cowell,<sup>4</sup> in England, Scheer,<sup>5</sup> in Germany, Wieland,<sup>6</sup> in Switzerland, and Kramer,<sup>7</sup> in the United States, should be mentioned. The clinical data available, however, upon the amount of irradiated milk necessary to protect human infants from rickets are inconclusive.

Since the results of our studies upon both infants and rats fed irradiated milk agree quite closely with Hess's and Lewis's results obtained at about the same time and with the same type of carbon arc lamp, we prefer for the present discussion to summarize them in a very few words.

In our studies of irradiated milk as in the other studies, two widely separated rat colonies were used with protective and curative experiments proceeding at the same time in both colonies. The standard methods of rat assay were used with the exception that varying amounts of 50 per cent cream were fed to the rats in place of whole milk or butterfat, as used by most workers. The object of using 50 per cent cream was to insure a somewhat more normal intake of salts than the usual rat assay includes. Since we could find little data upon the antirachitic potency of irradiated skimmed milk, we fed it in varying quantities to different groups of rats. From the results of these studies we concluded, as expected, that the antirachitic power of the irradiated whole milk lies almost entirely in the butterfat, since even large quantities of skimmed milk had little effect in either protective or curative experiments.

The method of irradiation was practically identical with that used by Supplee, Hess, and Lewis, and we are indebted to Dr. Supplee for his assistance in the arrangements. The milk was passed twice in

a thin film (approximately 0.4 cm.) over a wash board cooler in a large pasteurizing plant, and was exposed for 16 seconds to a carbon arc lamp in such a way that each c.c. of milk received a total of about  $2\frac{1}{2}$  million ergs, between 2,000 and 3,000 Angström units.

In this study the mixed pasteurized milk used for a control experiment contained on the average, 6 units of vitamin D per quart. The irradiated milk fed as 50 per cent cream to rats in the two separate colonies, in both preventive and curative experiments, contained on the average 65 units of vitamin D per quart of milk; an amount slightly higher than that found by Hess and Lewis. Throughout the present studies we have used the Steenbock unit for vitamin D in recording the rat assays.

The clinical studies were made upon infants resident in St. Vincent's Hospital, a large foundling home. Those chosen ranged between birth and 6 months of age at the time of starting the experiment. They remained constantly in a ward where it was not possible for direct sunlight to reach them, and where any possible effect of skyshine was excluded by glass and screening. For 2 hours each day, however, during 3 summer months they were placed in a low roofed, screened pavilion, which was so placed with reference to surrounding buildings that no direct sun whatever touched it and skyshine was also excluded. All antirachitic agents were withdrawn 6 weeks before commencing the experiments, which to date have continued for a period varying between 6 and 8 months, beginning from February to April, and continuing to the following October. We have planned to continue the experiments for the full circle of a year.

Physical and X-ray examinations were made at the beginning of the period and repeated monthly. The clinical criteria used in estimating the presence of rickets were those suggested by Hess. The most critical interpretation was placed upon the X-ray readings. It was not possible to obtain blood calcium and phosphorus determinations. A small control group with no antirachitic agents was started but unfortunately most of these babies were discharged too soon to be counted in the study. Formulae were left unaltered so that the group receiving the test milk might be comparable to those remaining on other antirachitic agents.

In Table I are shown the results at the beginning of the test period, and 6 to 8 months later clinical and X-ray diagnoses were made separately; one examiner having no knowledge of the other's findings. For the purpose of saving time and space the intermediate examinations are not recorded here. Clinically no child ever showed evidences

of rickets greater than that frequently seen in children in private practice on what is considered adequate antirachitic therapy with cod liver oil or viosterol. By X-ray examination no persistent active rickets whatever was found. We recognize of course that the last readings here reported were made in October and for final estimation the work is to be continued through the ensuing winter.

The infants grew satisfactorily and a distinct general impression was gained by an independent observer that their physical condition was superior to that of the infants on cod liver oil.

Owing to the loss of the small control group it is not possible to show the presence of rickets among an identical group. It is obvious, however, that under the given conditions rickets will develop unless adequate antirachitic therapy is resorted to. It is customary in the institution to give from  $\frac{1}{2}$  to 1 teaspoonful of cod liver oil daily and among the older infants and young children the presence of moderate rickets is seen frequently, and severe rickets occasionally.

A small group of markedly rachitic infants have been treated in the wards of the University and Children's Hospitals with irradiated milk as the only antirachitic agent. Prompt healing has occurred in each instance.

We are continuing such studies both protective and curative with a larger group of infants for the purpose of determining more accurately if possible the interrelationship of the human factor and the antirachitic factor particularly as to the quantitative relationship of the antirachitic factor in milk.

In connection with the direct irradiation of fluid whole milk we are carrying on studies with rats concerning the effect of irradiation upon vitamins A and B<sub>1</sub>, and with guinea pigs concerning its effect upon vitamin C. As far as we have been able to determine, irradiation with the carbon arc lamp as outlined previously in this paper has no destructive effect upon either vitamin A or vitamin C. Our studies have not yet been completed upon its relation to vitamin B<sub>1</sub>.

We are unable as yet to report a protective study upon a group of infants fed upon "yeast milk." Our experience so far with this antirachitic agent has been concerned with rat assays and a few rachitic infants. These confirm the favorable results reported by Hess,<sup>2</sup> and Wyman,<sup>6</sup> and others. The milk used for the rat assays was a commercial "yeast milk" bought on the open market.

The studies concerned with milk from cows irradiated with the carbon arc lamp present the most interesting data. Gowen<sup>9</sup> and his coworkers in 1926 exposed cows for 15 to 30 minutes to ultra-violet rays (type of lamp not mentioned) and reported the cure of rickets in chicks with this milk. Milk from unexposed cows did not cure control chicks. In the same year, Falkenheim<sup>10</sup> and his coworkers reported that milk from cows exposed to a mercury vapor quartz lamp had definite antirachitic power, whereas unexposed control cows produced milk with practically no antirachitic power. Supplee<sup>11</sup> reported that milk produced in summer has greater antirachitic potency than winter milk, and suggested that irradiation of the cow in the sunshine is responsible, but also mentioned that the influence of summer food might be a factor. Steenbock<sup>12</sup> and his coworkers conducted careful studies concerning the effect of irradiation of cows by the sun and by the mercury vapor quartz lamp upon the antirachitic potency of their milk. Their general conclusion was that irradiation of the cow with sun or artificial ultra-violet rays does not affect the vitamin D potency of the milk. In one series of experiments they felt there was a slight increase of vitamin D in the milk. On the other hand, they had reported in previous studies<sup>13</sup> that the antirachitic potency of goat's milk could be increased 24 times by irradiation of the goat with a mercury vapor quartz lamp. Hess<sup>14</sup> has also reported that irradiation of a nursing mother by means of a mercury vapor quartz lamp increased the antirachitic potency of her milk.

In our own studies we have used the carbon arc lamp of the same type as mentioned in the direct irradiation of fluid milk. This lamp differs from the mercury vapor quartz lamp in that it has a continuous spectrum and an intensity many times greater than the mercury lamp. There were 50 cows in the experiment and they had all been fresh

from 2 to 6 months. The cows were turned out for 3 hours daily into a shady orchard where there was no grass, and both the experimental group and the control group were fed on 20 per cent grain ration with mixed hay. The experimental group of cows was irradiated for 2 weeks before their milk was used for the studies and the irradiation was continued over the entire 9-month period.

Showing irradiation of cows with carbon arc lamps

The arrangement of the lamps with respect to the cows which were being irradiated is shown in Figure I.

FIGURE I

Cow	Lamp	Cow	Cow	Lamp	Cow	Cow	Lamp	Cow
-----	------	-----	-----	------	-----	-----	------	-----

It will be noted from the diagram that it was possible to irradiate 6 cows at once with this arrangement of stalls and lamps. The stalls were formed by the use of 2" pipe set into the yoke rack at the front and extruding almost horizontally to the rear where the pipe was bent downward and fixed into the floor. The accompanying photograph illustrates the method of irradiation. The cows could be brought in or taken out without touching or moving the lamps, thereby keeping them in operation continuously and affording a quick and easy method of irradiating a large number of cows in a short period of time.

The lamps were hung so that the arc formed between the two carbons was opposite the under side of the cow's body about midway from front to back. A good exposure of the udder side and the more tender portions on the under side of the body was thus obtained. The

Irradiated yeast to cow—200,000 units	160	1,600	—
<i>For comparison</i>			
3 teaspoonfuls cod-liver oil	200	2,000	Complete protection
10 drops viosterol	800	8,000	Complete protection

arcs were about 25" from the cows, at which distance the total ultra-violet intensity between the range of 2,000 to 4,000 Angström units was 6,400 micro-watts per sq. cm., or 640 ergs per sq. mm.

Each cow was irradiated for 15 minutes each day on one side only.

The assays upon the two separate rat colonies mentioned showed an average number of 22 units of vitamin D per quart of milk from the irradiated cows. The milk from the control group of cows showed an average of 5 units of vitamin D per quart of milk.

Table II records the results of the protective experiment upon 21 infants over a 6- to 8-month period; practically parallel to the infants fed upon irradiated milk. The same rigid requirements for clinical and X-ray diagnoses were maintained and a protective record almost equivalent to the infants fed irradiated milk may be noted in this table.

In addition to this protective study with milk from irradiated cows we have been much interested in determining the curative potency of such milk and have been surprised to find a similar curative power in infants with florid rickets. The laying down of the calcium in the zones of temporary calcification has been slower than with other anti-rachitic agents, but the bones have proceeded to complete healing. These infants have been followed in the hospitals mentioned and the blood calcium and phosphorus determinations have corresponded with the progress of the healing bones.

We prefer to obtain more data including both protective and curative experiments before making conclusive statements upon the anti-rachitic potency of milk from irradiated cows because of the previously unfavorable reports. However, we feel sanguine of its protective value. In Table III are listed the vitamin D units obtained by various investigators and including the present studies upon vitamin D fortified milk.

#### COMMENT

Our findings, particularly those concerned with the milk from irradiated cows, suggest that an even greater discrepancy may exist between the rat assays of antirachitic agents and their clinical value in the prevention and cure of human rickets. The prevention of rickets in a group of 21 infants under hospital control by means of 22 units of vitamin D per quart of milk from irradiated cows, would appear to necessitate further investigations of the unmeasured factors involved and further studies of the vehicles used for administration of vitamin D.

From the table which Hess and Lewis<sup>1</sup> published concerning irradiated milk, it is quite obvious that a number of the youngest infants they studied must have been receiving only 35 to 40 units of vitamin D per day, and yet the protection recorded was highly satisfactory. This number of units is not far in excess of the number of units of vitamin D administered to our group of 21 infants fed upon milk from irradiated cows.

Direct irradiation of milk can be carried out only where larger pasteurizing plants are available. In such places this would seem the method of choice, since it would afford, particularly to those of moderate means, a potent source of vitamin D at a cost only slightly above that of ordinary milk and at the same time assure its reaching the infant. Irradiation of the cow has certain advantages over this method. The danger of change of taste, alteration of chemical nature, destruction of other vitamins and some contamination by handling are all eliminated. It is equally suitable for use in those carefully controlled herds producing certified milk and herds in smaller communities producing a good grade of raw milk. Either method offers an appreciable saving of expense for institutions caring for a large number of infants such as that in which these experiments were conducted.

"Yeast milk" though higher in number of vitamin D units, is apparently no more efficacious per quart of milk for protection and is more expensive to produce.

We have had no experience with the method of adding vitamin D directly to the milk. We are interested now in comparing this method to those above, with especial reference to the number of Vitamin D units necessary to obtain equivalent results.

#### SUMMARY

The discrepancy has been emphasized again between the rat assays of antirachitic agents and the protective and curative value of such agents for human infants.

Three types of vitamin D fortified milk were studied; namely (a) irradiated pasteurized milk, (b) "yeast milk," and (c) milk from irradiated cows. Parallel studies were conducted on rats with all three types, and studies on infants with the first and third types. Some curative studies, however, were made upon infants with "yeast milk," the second type.

The amount of vitamin D by assay and the protection afforded infants against rickets by the first two types were found to be equivalent in most respects to the favorable results reported by other investigators.

Preliminary investigations of milk from irradiated cows, both by rat assay and by protective and curative experiments on human infants would suggest a definite increase in vitamin D potency over the milk from control cows. Twenty infants over a period of 6 to 8 months were protected from rickets by this antirachitic agent alone. One infant in the foundling home and a small number of other infants with definite rickets were cured by this same agent alone. We do not regard these data as conclusive until the group of infants has been followed for a longer period.

The rat assay on milk from irradiated cows approximated 22 units of vitamin D per quart of milk. The apparent effectiveness in preventing rickets in infants by such a small number of vitamin D units emphasizes the importance of certain unknown and unmeasured factors in vitamin D fortified milk which deserve further consideration and study.

**T**UBERCULOSIS has been aptly termed the "Foe of Youth" and to fight this foe is the important work which more than 2,000 affiliated tuberculosis associations all over the country carry on throughout the year. It is to maintain this work and to continue to promote the organization of measures that will prevent the untimely death of so many thousands of our young people, that the penny Christmas seals are sold each year at this time. Each year brings improvement and with it the chance for a longer, happier life for all of us.—N. T. A., New York.

# A Study of Lobar Pneumonia in Massachusetts: Methods and Results of Pneumococcus Type Determination, 1931-1932\*

RODERICK HEFFRON, M.D., AND FLORENCE M. VARLEY

*Pneumonia Study and Service, State Department of Public Health, Boston, Mass.*

EARLY in 1931 a study of lobar pneumonia in Massachusetts was begun. This study,<sup>1,2</sup> financed by the Commonwealth Fund of New York City, comprises a study of the epidemiological factors involved in the spread of the disease; the production of concentrated antipneumococcic serum for treatment; and the organization of various areas of the state, selected by our Advisory Committee on Lobar Pneumonia. In them pneumococcus typing can be carried out so that patients may receive the benefits of early serum treatment.

Eleven selected areas have been organized embracing a population of about 2 million or approximately one-half that of the state. They include urban, rural, industrial, residential, seashore, and upland regions. It was decided to use the laboratories of the one or more centrally located hospitals of each area as the typing center for that area. The present paper will deal with the findings of the 20 laboratories coöperating in this work.

In order to obtain uniform and proficient technic in this work, the technicians were sent to Boston and trained in pneumococcus typing at the Boston City Hospital. Typing is carried out for Types, I, II, III and V (V, because of occasional cross-agglutinations with Type II). Pneumococci other than I, II and III are reported as Group IV. Cultures of Group IV are sent to the State Bacteriological Laboratory where typing is carried out to the full 32 (Cooper<sup>3</sup>) types, to determine their geographical distribution and frequency. Incidentally, this affords a measure of checking the accuracy of the typing in the outlying laboratories, for if a culture is sent in as a Group IV and turns out to be a I, II, or III, it is obvious that an error has been made.

A set of directions was drawn up and copies were supplied to each

\* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

## Krumwiede and Mouse Typing

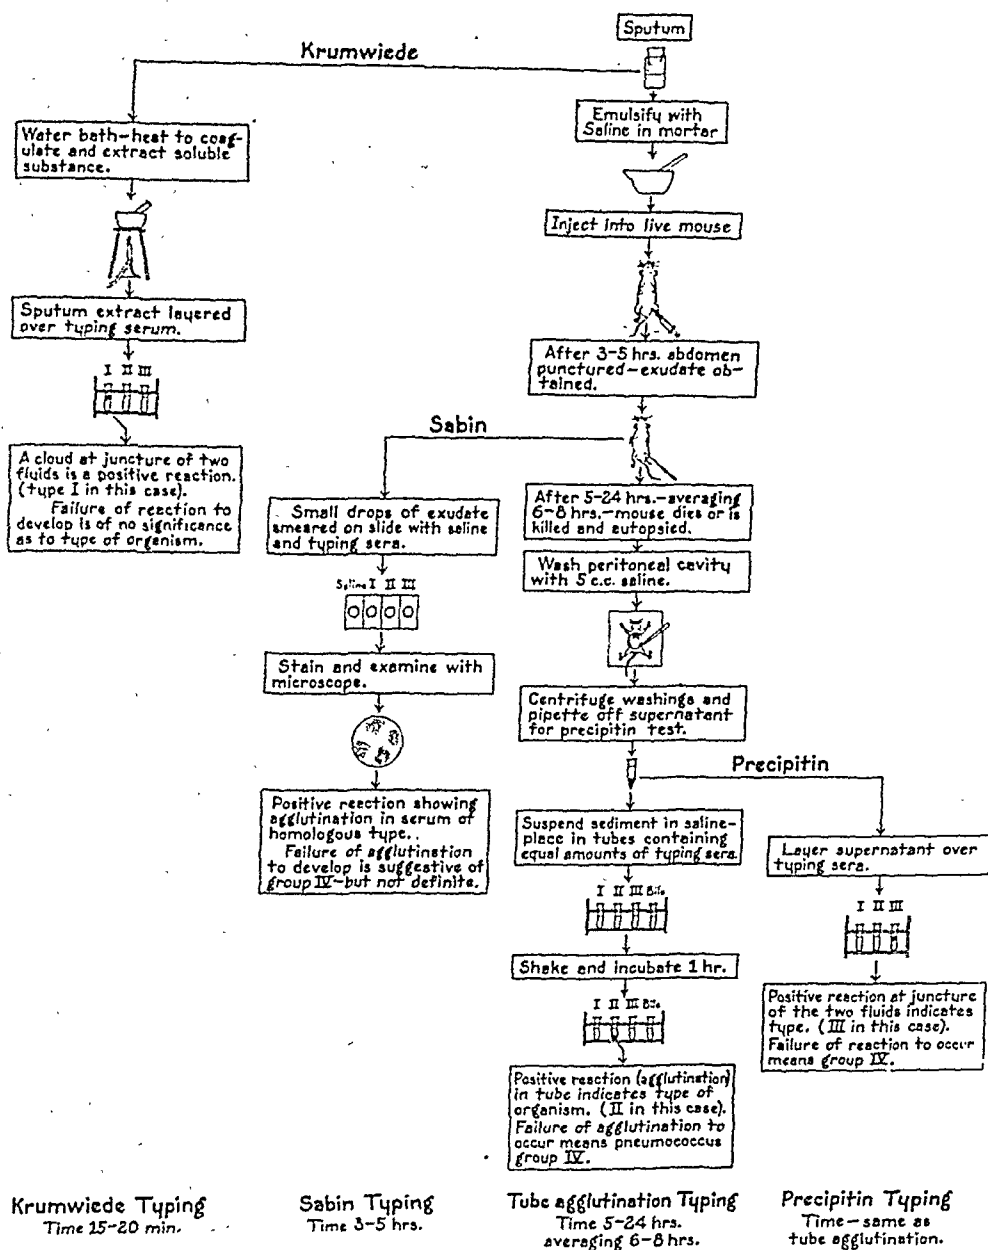

FIGURE I

technician. These give detailed procedure for typing sputum by the Krumwiede,<sup>4</sup> Sabin,<sup>5</sup> tube agglutination and precipitin methods<sup>6</sup>; and for typing material obtained from blood, throat, and other cultures, spinal and chest fluids, pus, and urine. The use of white mice in typing sputum and other suitable material has been adopted.

Given sputum, the technicians have been requested to try on each.

specimen the Krumwiede, Sabin, and tube agglutination methods in the order named. Either the Sabin or tube agglutination acts as a check on the result of the previous method employed. An attempt was made to have every typing in these outlying laboratories checked by typing the organisms obtained from cultures of the mouse's heart blood or peritoneal exudate in plain or blood broth, or on blood agar plates. This has been done in some laboratories and neglected in others.

To familiarize the physicians of the state with some of the methods of typing sputum and urine, two sheets of illustrations showing schematically the methods used and the usual time necessary to perform each have been distributed at large (Figures I and II).

#### TYPING RESULTS IN OUTLYING LABORATORIES

The number of typings in the laboratories of the areas over the state during the past fall, winter and spring is as follows:

<i>Area</i>	<i>Number of Typings</i>
(1) Beverly	30
(2) Malden	43
(3) Chelsea	(data not available—small number)
(4) Newton	45
(5) Boston	204
(6) Brockton	19
(7) New Bedford	13
(8) Ayer	32
(9) Worcester	122
(10) Pittsfield	10
(11) Great Barrington	3
Total	521

Areas 2, 7 and 9 were not organized until well into the winter.

The distribution of types was as follows:

Type I	79
Type II	26
Type III	50
Group IV	362
No pneumococci	
Streptococci	
Friedländer's bacilli	
Total	517 *

\* This figure is smaller than the total of 521 typings attempted because 5 specimens were urine. These gave negative precipitin reactions.

At first no request was made that cultures of all Group IV be sent to the State Bacteriological Laboratory for further typing. During the early winter such a request was made, and since cultures of most of Group IV have been obtained.

One hundred and seventy-one cultures have been received from the outlying laboratories and typed out to the full 32 types. (Table I.)

† 3 sent to see if they were VIII

\*\* 1 culture gave cross-agglutination with X and XX serums and is reported in both types.

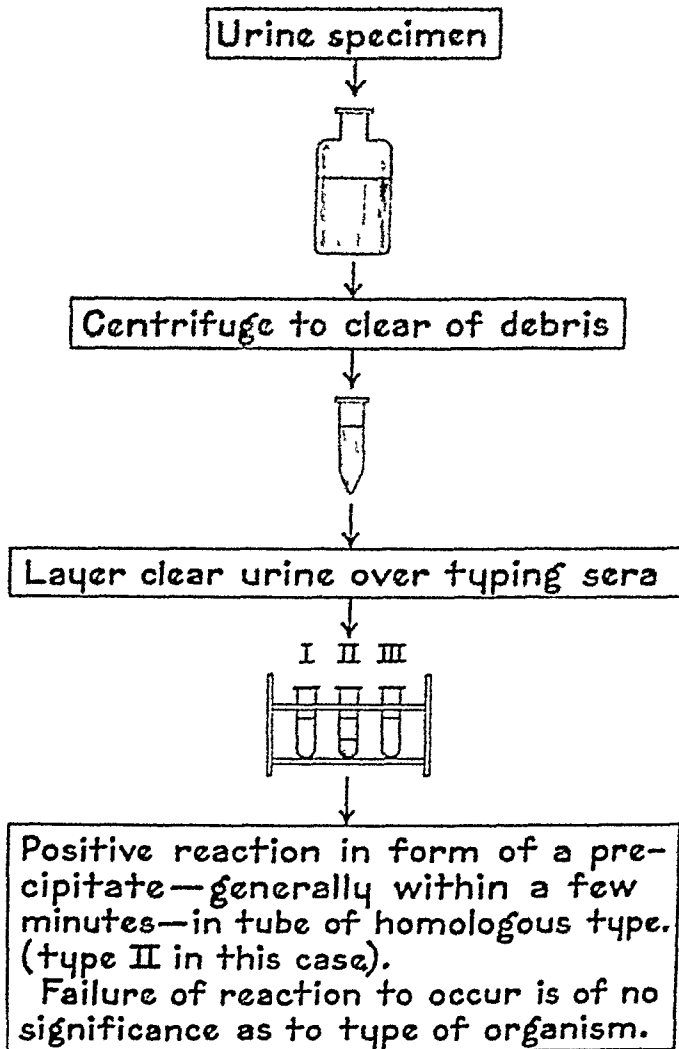

Among the cultures sent in, only 2 of Type I and 1 Type III were sent in as Group IV.

#### STATE BACTERIOLOGICAL LABORATORY TYPINGS

During the past year typing has been carried out to the full 32 known types at the State Laboratory on all material sent there for this purpose. In the spring the demand became so great that an additional bacteriologist was taken on for this work.

The typings at this laboratory during the past year may be divided into 3 groups: (1) those done on Group IV cultures sent in from the outlying laboratories, (2) those on sputa sent in by the District Health Officers associated with this department, from

# Urine Typing

**Urine precipitin typing**  
Time—15-20 minutes.

FIGURE II

patients with lobar pneumonia cared for at home, and who are not receiving antipneumococcic serum, (3) the group of "regular" typings carried out on material of various sorts sent directly by physicians at large. (Table I.) The specimens in this last group have not all come from cases of lobar pneumonia; many are from cases of broncho-pneumonia and other respiratory diseases; conse-

FIGURE III

quently, the frequency with which any particular type is observed cannot be compared with the reported occurrence of various types as the etiological agents in cases of lobar pneumonia alone. (Figure III.) This group represents a true picture of the variety of materials from hundreds of cases sent for typing by physicians of this state, and probably yields a picture similar to that which may be found by other state laboratories undertaking such work, and gives definite evidence that in Massachusetts, nearly every known type of pneumococcus can be found associated with respiratory disease.

Every specimen of sputum, chest or spinal fluid, or pus, received for typing which has yielded good pneumococci has been typed by one or more methods, and a vigorous attempt made to check each by cultures from the heart's blood of the mouse in plain or blood broth or on blood agar plates.

The routine methods employed on sputa have been (1) Krumwiede, (2) Sabin, and (3) tube agglutination, with or without precipitin test. (The final report to the physician on the result, if not previously rendered, was given here.) (4) In a few cases, typing has been done from heart's blood cultures, where the above methods have failed, (5) Occasionally, typing has been done from individually fished colonies.

The Sabin and tube agglutination (with or without the precipitin test) methods were used on chest or spinal fluids and pus. They were also cultured in broth and on blood agar plates directly.

On sputa, frequently the first 3 were done before checking from cultures, in order that an attempt might be made to evaluate the speed, accuracy and applicability of these various methods. The results will be discussed later.

A list of the organisms found in the sputa obtained from patients with lobar pneumonia who were cared for at home will be seen in Table I. These specimens were sent by the District Health Officers, and came from widely separated areas of the state. Data

concerning the case fatality rates, incidence of complications, and so forth, are being gathered upon this series which will give definite information upon this particular group of little known and much debated cases.

In Table I it will be noted that the term "Group IV" appears near the bottom of the table. In all such instances the specimens were inoculated into mice. Pneumococci could be seen in the mouse peritoneal exudate, but due to the overgrowth of other organisms, which increased in numbers upon further cultivation and exterminated the pneumococci, they could not be classified as to type. Unfortunately, the number of such was rather large.

If no pneumococci could be seen in direct smear of the mouse exudate, the report was "No pneumococci found." Hemolytic streptococci and Friedländer's bacilli were never reported, the former because they occur so often in normal throats their significance is uncertain, and the latter because there was no diagnostic serum available for the types known to be pathogenic for man. Such agglutinating serum has been obtained and henceforth Friedländer's bacilli will be reported. Records were kept where they were found and these findings are included here. No record has been made of *S. viridans*, nor of *B. influenzae*, when found. These organisms have occurred in varying numbers and there is great doubt of their clinical significance in the numbers found.

The third and last group of typings is the so-called "regular" done on sputum and other specimens sent directly to the laboratory. The results give an excellent gross picture of the variety of organisms likely to be encountered.

Among the "regular" typings the specimens upon which typing was requested were as follows:

	<i>Number</i>
Sputa	691
Chest fluids	8
Urines	7
Spinal fluids	5
Cultures of blood or pus	5
Total	716

It must be emphasized that the above specimens did not all come from cases of lobar pneumonia, but from many sorts of respiratory disease. The organisms reported are given in Table I.

The group of "regular" typings in Table I includes 15 instances where 2 types were isolated from the same specimen or definite cross-agglutination between 2 types occurred. These are reported under both types. The results of examination of 7 urines negative for I,

II and III, and of 8 specimens in which too few pneumococci were found to be typed are not included.

Summarizing the results of the "regular" typings noted in Table I, the distribution of the specimens as to organisms found is:

	Number	Per Cent
Pneumococci Types I to XXXII	464	64.7
Reported as "No pneumococci found"	134	18.7
Reported as "Group IV" pneumococci	77	10.8
Streptococcus hemolyticus	31	4.3
Friedländer's bacilli	7	1.0
Pneumococci—typical—but could not be typed with any of the 32 diagnostic sera available	3	0.4
Total	716	99.9

### SEASONAL INCIDENCE

In an effort to determine the relative frequency with which the various types of pneumococci and other organisms occurred during the different seasons a series of charts have been prepared on which their monthly incidence has been recorded for 11 months, September 1, 1931, to July 31, 1932. Two groups of specimens have been combined. The results from sputa sent in by the District Health Officers have been added to those of our "regular" typings, as all of these specimens were sent to the laboratory directly from patients. (No Group IV cultures from outlying laboratories are included.)

The following charts (Figures IV to VII) give occurrence by months of the various organisms found in percentages, and show the

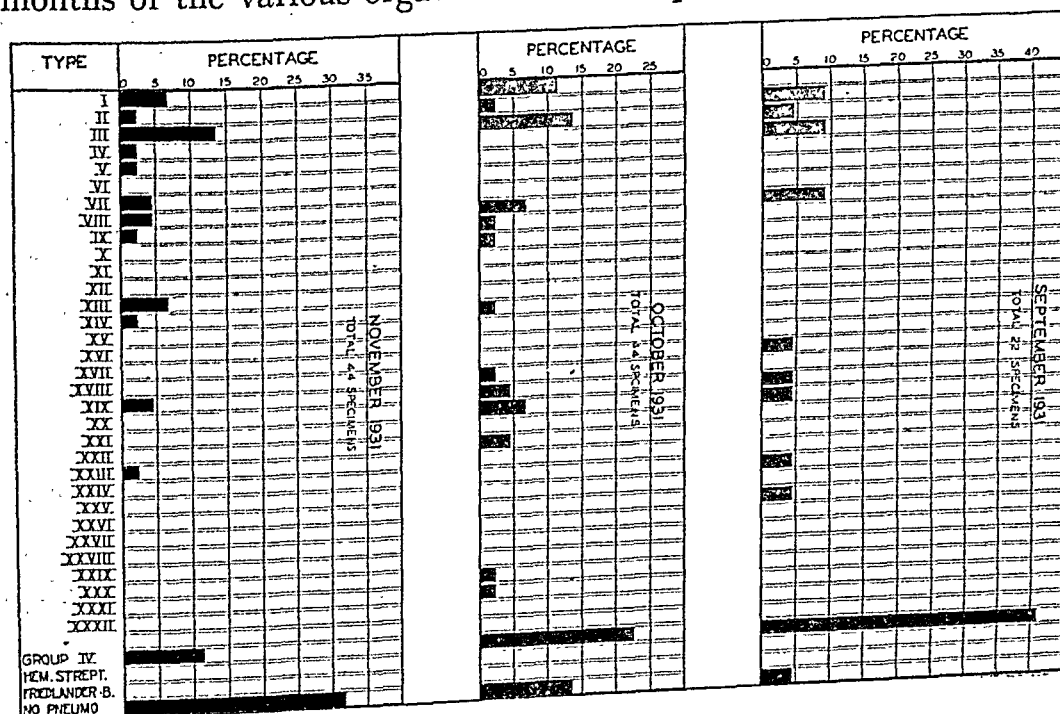

FIGURE IV

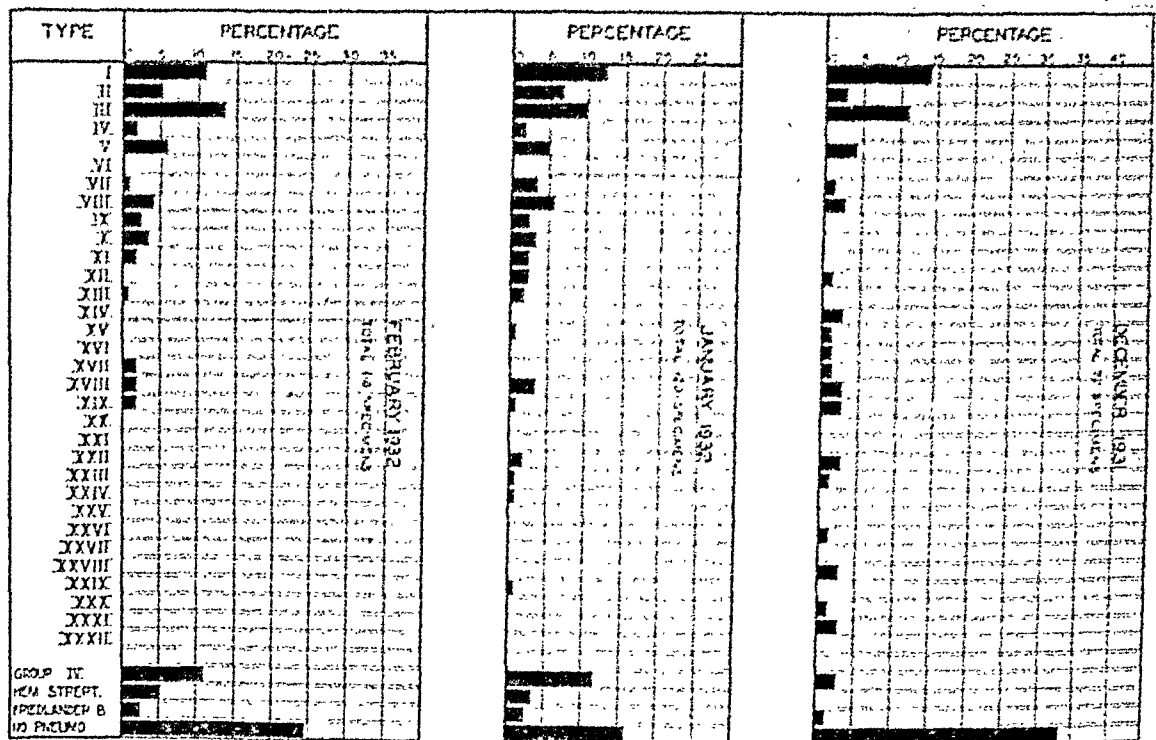

FIGURE V

results of typing 789 specimens. The various sub-types (IV to XXXII) were found more frequently during the winter and spring months December to May, than during the warmer months.

The approximate figures for this may be found in Table II. It will be noted that the percentage incidence of the sub-types (IV to

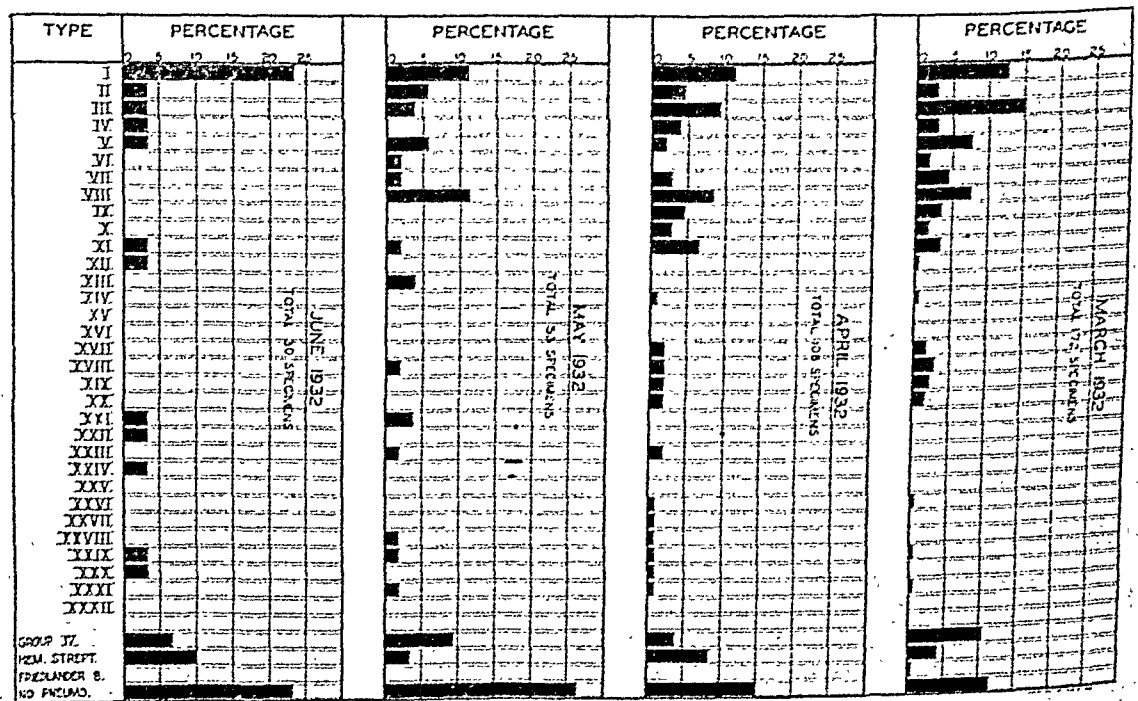

FIGURE VI

XXXII) remains more constant than does the actual number of different sub-types found; also, that Types I, II, and III comprise less than a quarter of the total 11 months' yield at the State Laboratory. There is every reason to believe that the figures for I, II, and III would be much greater were these typings done on consecutive cases of lobar pneumonia only.

TABLE II

Month	Percentage of Types Found (Approximate)		Percentage of Group IV and Other Organisms (Approximate) Per Cent	Actual Number of Different Sub-types Found
	I, II and III Per Cent	IV to XXXII Per Cent		
Sept., 1931	13.6	40.7	45.4	7
Oct.	27.3	36.2	36.3	10
Nov.	22.6	31.7	43.2	9
Dec.	27.8	35.0	37.5	16
Jan., 1932	29.2	37.3	33.2	16
Feb.	30.5	26.1	43.2	11
Mar.	30.7	43.1	26.8	17
April	25.4	46.4	27.4	19
May	20.8	39.8	39.6	12
June	29.9	29.7	40.0	9
July	0.0	37.5	62.5	3
Approximate average for all 11 months	23.4	36.6	39.5	11.7

The lower chart in Figure VII summarizes the results for 11 months and shows the percentage incidence of the various organisms found September 1, 1931, to July 31, 1932—a total of 789 specimens including 764 sputa, a few chest and spinal fluids, a few urines, and blood cultures.

#### GEOGRAPHICAL DISTRIBUTION OF TYPES FOUND

There has been no especial geographical distribution among any of the 30 types of pneumococci found. The same type was isolated from individuals ill at the same time in widely separated regions of the state without apparent contact having occurred between the hosts.

Every type of pneumococcus (Cooper types), excepting XXV and XXXII, has been found among the specimens sent to the State Laboratory.

#### MULTIPLE FAMILY CASES OF LOBAR PNEUMONIA

Instances where 2 or more members of the same family have had lobar pneumonia within a few days or weeks of each other due to the same type of pneumococcus, have been decidedly uncommon and occurred only four or five times among nearly 1,000 cases typed either by our collaborators or at the State Laboratory.

## ACCURACY OF TYPING METHODS

It is difficult, if not impossible, for us to give other than an estimation of the accuracy of the various methods of typing used. It is our experience that when the results of a typing by the Krumwiede, Sabin, or tube agglutination method are definitely positive, they are over 99 per cent accurate. The reporting of indefinite results leads to error and is to be discouraged.

The following figures throw light upon this attempt to estimate accuracy. The number of typings by the method used and the number of these checked by another method or by culture is indicated. Where a definite type has been determined and later yields a different one (not including cross-agglutinations and specimens with 2 types) on culture, such findings are indicated as discrepancies and for all practical purposes may be counted as errors in typing.

Typing Method	No. of Specimens Yielding Types	Total No. of Typings Checked	
		Those in Agreement with Original Type Found	Those NOT in Agreement with Original Type Found
Krumwiede	57	53	3
Sabin	380	360	4
Tube agglutination	150	143	2

The Krumwiede takes from 30 to 60 minutes. The Sabin usually gives positive results in 5 to 8 hours. The tube agglutination and/or the precipitin method can be done from 6 to 24 hours after inoculation of the mouse.

## ADVANTAGES AND DISADVANTAGES OF METHODS

*Krumwiede method of typing sputa:* This method, when positive, yields a very speedy result. Usually, however, it has been found that the sputa sent to the State Bacteriological Laboratory for typing are insufficient in amount for this method, or when boiled become cloudy or otherwise unsatisfactory. For these reasons the usefulness of the Krumwiede has been greatly decreased. With some attention paid to the gathering of suitable specimens in satisfactory amounts it should be possible to increase greatly the number of positive typings by this very valuable rapid method.

Figure VIII shows the small number of positive Krumwiedes obtained from 683 sputa, being only 7.9 per cent of the whole (Krumwiedes were not done for Types IV to XXXII). The method yielded 30 per cent positives for I, II, and III among those sputa

from which a satisfactory supernatant fluid for layering was obtained. For any individual laboratory, in close association with patients, it should be possible to better this record with ease.

The results of the Krumwiede method of typing among sputa later proved to contain Type I, II, or III pneumococci are shown in Table III.

TABLE III  
RESULTS OF TYPING BY VARIOUS METHODS

Results with specimens containing	Krumwiede				Sabin				Tube Agglutination			
	No. of specimens available	No. tried	No. positive	Per cent positive among those tried	No. of specimens available	No. tried	No. positive	Per cent positive among those tried	No. of specimens available	No. tried	No. positive	Per cent positive among those tried
Type I	89	31	24	77	83	73	69	95	44	44	40	91
Type II	35	14	12	86	27	25	24	96	12	12	11	92
Type III	74	27	18	67	63	54	51	95	34	34	31	91
Types IV to XXXII inclusive	...	...	...	...	255	253	232	92	93	74	66	89

*Sabin method of typing specimens:* In our experience this method will give a positive result on the largest number of specimens (sputa, chest, or spinal fluids, pus, and so forth) in the shortest period of time of any used; and is readily learned by new technicians.

Figure IX shows the results with this method. A total of 778 specimens were received which might have been put into mice, but due to the character and age of some this procedure was not always followed out though seven hundred and thirty-one were inoculated into mice. Sabins were not done on all of these for various reasons, the principal one being that in a large number of cases examination of the mouse exudate showed a very mixed growth or no pneumococci. Of the 731 specimens, 448 were tried with typing sera (this number includes 43 which never yielded a pneumococcus of any kind and 7

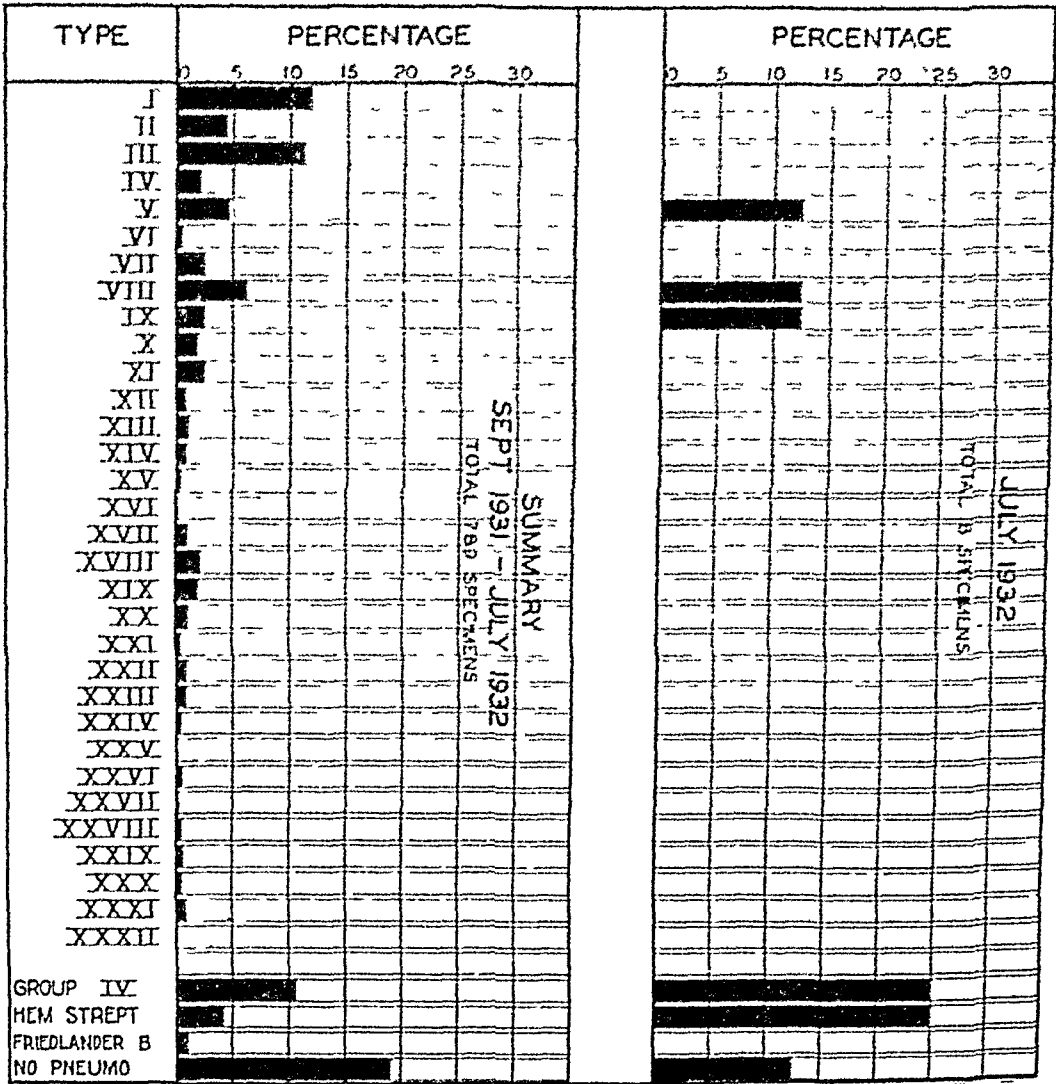

FIGURE VII

tried only for I, II, and III which later yielded a higher type). Of the 778 specimens, 376, or 48.3 per cent, gave a positive result for some type, or 83.9 per cent of those tried. Of those tried, 22 were negative and later on culture or tube agglutination yielded some definite type.

In estimating the efficiency of the Sabin method it is found that

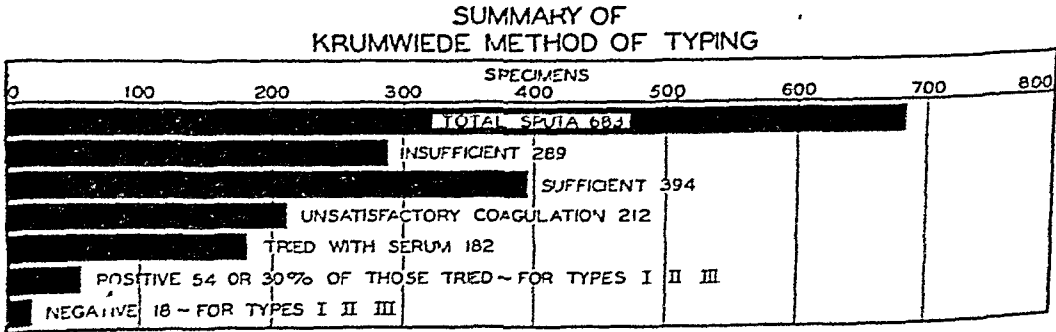

FIGURE VIII

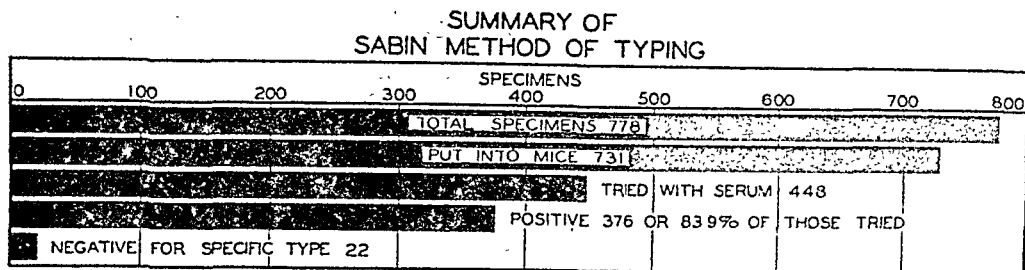

FIGURE IX

among 398 specimens that contained some definite type of pneumococcus, 376 or 94.5 per cent gave a positive result.

The results of the Sabin method among specimens proved to contain pneumococcus of some definite type (from I to XXXII) may be seen in Table III.

*Tube agglutination method of typing:* This method offers no particular advantage except in occasional instances where the Sabin has been negative, due chiefly to the presence of mixed culture. Of course, the tube agglutination is an old and well tried method and as such has rendered, and still does render, invaluable service. The great disadvantage lies in the fact that so much time is required for its performance.

Owing to the lack of time during the past year tube agglutinations were omitted on some specimens when satisfactory results were obtained by the Krumwiede or Sabin. These were checked by cultures, usually heart's blood cultures from the mouse. There were 273 specimens on which our records for tube agglutinations are complete. (See Figure X.) Of these, all 273 were tried. One hundred and forty-eight or 54.2 per cent were positive which is also 54.2 per cent of those tried. Sixteen of the negatives contained some specific type. Of the remaining 109, 90 never yielded a definite type by any method and the others were not typed out far enough to include the specific type later obtained from culture.

The results of tube agglutinations among specimens proved to contain pneumococci of some definite type (I to XXXII) are shown in Table III.

FIGURE X

*Other methods of typing:* The precipitin test as an aid to typing (using the supernatant of centrifuged mouse peritoneal exudate washings) has been used occasionally and was most useful where the mouse peritoneal exudate contained other organisms with the pneumococcus.

Occasionally Avery broth cultures (the so-called artificial mouse method of typing) have been made simultaneously with mouse inoculations, using the same specimen. Such data are being collected and will be reported later.

#### CHECKING BY CULTURES

Efforts were made to check every type previously determined from a culture of the organism. Among 789 typings only 43 or 5.4 per cent were not checked by either some other method of typing or by culture, and most of these were checked from cultures of the organism. The majority of such cultures were made from the heart's blood of the mouse in plain or blood broth or on blood agar plates. Most of those not checked could not be typed by any rapid method due to the presence of other organisms; the type was ascertained from cultures of individually fished colonies or cultures of the heart's blood of the mouse.

#### MISCELLANEOUS FINDINGS

Two distinct types of pneumococci have been isolated from 4 specimens, culture of the mouse's heart blood yielding a different type from that obtained by one or more of the rapid methods of typing. In each case both types were obtained by more than one method. In 3 other instances pneumococci have been found in conjunction with another organism, both in the mouse's peritoneum and in the heart's blood culture. The list follows:

##### PNEUMOCOCCUS TYPES OR OTHER ORGANISMS

<i>Number</i>	<i>Type</i>	<i>Type</i>
1	III from peritoneal exudate;	XX from heart's blood
1	III from peritoneal exudate;	V from heart's blood
1	IX from peritoneal exudate;	V from heart's blood
1	I from peritoneal exudate;	II from heart's blood,
2	III with Friedländer's bacilli	
1	IV with Friedländer's bacilli	
1	XXVI with <i>Streptococcus hemolyticus</i>	

Many of the above findings were also verified by culture of individually fished colonies. Due to the great amount of time which must be used in carrying out this type of work little has been done in this direction.

Since the figures in this article were compiled, a single Type I

colony has been isolated from the heart's blood culture of a reported Type XXII (by Sabin). The heart's blood broth culture gave a negative I and a positive XXII macroscopic agglutination. The heart's blood was also streaked on to a blood agar plate from which colonies of Type XXII and a single colony of Type I were isolated. Similarly, a strain agglutinating with both X and XI sera has been isolated from a reported Type I.

In seven other instances cross-agglutination occurred in the Sabin. Two of these strains were never obtained in pure culture. Two lost their dual characteristics upon cultivation and later agglutinated only with 1 type serum. The other 3 (isolated by single colony fishing) maintained the property of cross-agglutination for as long as they were kept, agglutinating with 2 sera both in the tube and by stirring on the slide. The types showing cross-agglutination were as follows:

- Types II and XIX
- Types IV and IX (never obtained in pure culture)
- Types VIII and XI (later, only XI)
- Types XI and XV
- Types XVI and XXVIII (never obtained in pure culture)
- Types XXVI and XXIX
- Types XXIII and XXX (later, only XXX)

#### DISCUSSION

A review of the bacteriological findings show that there has been a large amount of work done on sputum examination and pneumococcus typing. Perhaps the major difficulty encountered was that of obtaining a satisfactory specimen of sputum (or other material) of suitable quality and quantity for typing. In the outlying laboratories less difficulty has been experienced as they are in much closer association with physicians and patients than is the State Laboratory, where over 90 per cent of the specimens come by mail. Roughly, one-half of the specimens sent for typing were 24 hours old on arrival, and most of the remainder were older. Among such old specimens, as is well known, pneumococci tend to be over-grown by other organisms and die out, thus making typing difficult if not impossible, and the isolation of pneumococci in pure culture very laborious and wasteful of time. Sputa received by ordinary mail during the warm months are especially difficult to type. Specimens of satisfactory quality and quantity should be specifically requested and if specimens cannot be brought by messenger they should be sent by special delivery mail.

To carry out pneumococcus typing on a large scale, a 24-hour service is, of course ideal, but is seldom obtained. In lieu of such an ideal service, arrangements have been made in the coöperating laboratories (in the areas organized for the serum treatment of cases of lobar pneumonia) to have all specimens arriving at night for typing, injected into mice at once in order that the typing may be done in the morning by the technician. Mice dying during the night should be placed in the refrigerator so that their peritoneal exudate will not be over-grown with *B. coli*. In most instances specimens arriving in the early evening have been typed that night.

At the State Laboratory the specimens for typing are taken from cases of all sorts of respiratory diseases, of many days' duration, so that with the majority of specimens the acute need of saving a few hours of time has not arisen. Even so, there was a sufficiently large number of specimens, from early cases of lobar pneumonia in which serum treatment was contemplated, to keep the laboratory force (2 workers) very busy during the pneumonia season, often working 12 to 16 hours a day during that period (January through April). An attempt was made to check every typing by cultures of the organism, obtained chiefly from the mouse's heart blood. In some instances as many as 5 different methods of typing have been done upon a specimen to ascertain the value of each method and afford data for a comparison of the methods. Typings are now reported to physicians as "Type I," "Type II," "Type III," "Group IV—type V," or whatever the sub-type happens to be, or "Group IV—type undetermined—advise another specimen."

When 2 types are obtained from a single specimen or cross-agglutination occurs, several things can be done to clear up the problem. Another specimen of sputum should be requested and the urine typed. From the clinical standpoint, cultures of blood and/or lung puncture, with the typing of any pneumococci found, will usually settle the matter.

The Krumwiede is a very valuable method of typing in that it is a great time saver. A negative Krumwiede is of no significance and neither a tentative nor final report of Group IV should be made upon this finding. A slight hazy ring or indefinite cloudiness at the line of juncture of the two fluids in the tube is not significant and should not be reported. About one-half of these "suggestive" reactions have later proved to be some other type. Seventy-five per cent of those sputa yielding a clear liquid for layering have been positive and about 25 per cent negative, for Types I, II, and III, some one of which was later found in the specimen.

The Sabin method is the most generally satisfactory and useful for accurate and rapid determination of type. Where pneumococci are seen in the mouse exudate but show no agglutination with Types I, II, or III sera, a tentative report of "Group IV" may be made and is nearly always correct. Considering Types I, II, and III only, the Sabin has failed while the tube agglutination has yielded a type, in about 1 of 75 instances. From observations made in various laboratories this proportion of failures might be expected to be greater, as most technicians do not stir the mixture of organisms and serum sufficiently before drying it.

Usually good pneumococci give a clear-cut result with the Sabin, and in such cases it has proved safe to assume the result correct. "Naturally occurring clumps" do sometimes occur, however, in one smear only and not in the others. In such cases experience is necessary for an accurate diagnosis. If there is any question as to the reading of the Sabin, it should be repeated. The reporting of indefinite results leads to error.

If the typing is being done out to the full 32 types, all should be tried on every specimen. At the State Laboratory during the rush season, we did not always adhere to this policy and were led into some difficulty with supposed cross-agglutinations which later turned out to be clearly one of the higher types not tried at the first typing. Subsequent checking with mouse's heart blood cultures confirmed these results. (Only those cross-agglutinations which were very definite in both types are recorded in the earlier part of this paper.)

A final report of "Group IV" should not be made until after the tube

agglutination method has been carried out, with incubation and frequent shaking of the tubes for 1, or preferably, 2 hours. Both undiluted and diluted sera should be set up. Freshly isolated organisms of high virulence occasionally do not agglutinate in diluted serum; sometimes they do not agglutinate in the undiluted, probably due to the "pre-zone" phenomena.

The tube agglutination method has not proved as sensitive as the Sabin and fewer positives were obtained with it than with the Sabin.

Considering Types I, II, and III only, as these are the predominating and the ones of greatest immediate or potential interest regarding the specific treatment of illness caused by them, it is found that among a total of 216 such types found, 9 errors were made. In 6 instances the report was "Group IV" and 1 was "No pneumococci found"; in 2 a Type III was reported as a Type I,--1 on the result of a "suggestive" Krumwiede (such as were later disregarded) and 1 on the result of a tube of agglutination. Those reported as "Group IV" and "No pneumococci found" yielded, with 1 exception, mixed mouse exudates and were finally typed from mouse's heart blood cultures or from colonies fished from cultures. One yielded a practically pure culture of Type I, both from the mouse's exudate and heart's blood culture, and had failed to give a positive result either by the Sabin or the tube agglutination method.

NOTE: We are much indebted to Edith Beckler, Director, Massachusetts State Bacteriological Laboratory, for the great aid and encouragement given us in carrying out this work. Likewise, Georgia Cooper of the New York City Laboratories has been very helpful in rendering valuable assistance in many ways. We wish to take this opportunity to express our thanks to both Miss Beckler and Miss Cooper for their many kindnesses.

Much of the diagnostic sera used throughout this work was obtained from Miss Cooper in New York City.

### CONCLUSIONS

1. Pneumococcus typing is being requested by increasing numbers of physicians in Massachusetts.

2. During the past winter all 32 (Cooper) types of pneumococci excepting Types XXV and XXXII were found.

3. There was no especial geographical distribution evident of any of the types found.

4. Multiple cases of lobar pneumonia occurring in the same family at approximately the same time were very uncommon.

5. The Krumwiede, Sabin and tube agglutination methods of typing were and still are largely used and were found to be over 99 per cent accurate when definitely positive.

6. The Sabin method of typing has given a greater number of accurate positive typings in a shorter period of time than any other method studied, and is a method readily learned by technicians inexperienced in this work.

7. Of 789 specimens typed at the State Bacteriological Laboratory during the 11 months, September 1, 1931, to July 31, 1932, the type of pneumococcus found was checked in 94.6 per cent of the cases by a second method of typing or from a culture of the organism.

8. The various sub-types (Types IV to XXXII) were found more frequently during the 6 winter and spring months, December to May, than during the warmer months.

9. In view of the results to date, and until conclusive proof to the contrary is

obtained, it is felt that every type determination done by the Krumwiede, Sabin, or tube agglutination method should be checked by some other method of typing. Typing the organism obtained from cultures of the mouse heart's blood affords the most valuable means of checking.

## The Private Practitioner and Preventive Medicine

NOTHING is more difficult than to determine the beginning or the end of great events. All we can say today is that we have been the witnesses of the greatest epoch of advance in the science and art of medicine of which there is any record in the history of mankind. Not the 5th century B.C. in Greece, nor the great 13th century in Europe, nor the Renaissance itself, can show a similar acquisition of new knowledge and its application as occurred in the hundred years following 1832. We can say even more: in no previous age has there been such growth of the conception of preventive medicine. . . .

When we reflect upon modern preventive medicine we naturally think of the change and improvement which has occurred in our external environment. We think of the great pioneers and their work for the provision of public and wholesome water supplies, for the isolation of the sick, the removal of nuisances, the reform of housing, drainage, sewerage and sewage treatment, the inspection of food, the Factory Acts, and vital statistics. Looking back we see what they did, and are more grateful than their contemporaries to Chadwick and Simon and Farr, to Bentham and the Mills, to Lord Grey, to Owen and Cobbett, to Lord Shaftsbury, and to the statesmen who took occasion by the hand. When we reflect again, our minds turn to the masters of physiology who illuminated the 19th century—to Helmholtz, Claude Bernard, and Carl Ludwig; they were followed by the masters of pathology, Virchow, Pasteur, and Koch. Perhaps we remember even the great clinicians who created and led professional opinion, Bright, Addison, and Hodgkin—the Guy's trinity—Gull and Jenner, Osler, Allbutt, and Barlow; and we wonder whether, after all, it is not the work of these eminent men which laid the foundations of prevention. Lastly, we are learning to see that preventive medicine owes an irredeemable debt to Edward Jenner, to the anesthetists Morton and Simpson, to the antiseptic principles of Lister, to the discoverers of the causes of disease, such as Pasteur, Koch, and Manson, and to the "immunizers" who followed them. . . . —Sir George Newman, *Brit. M. J.*, July 30, 1932, p. 190.

# Incidence of Tularemia in New York State<sup>\*</sup>

RUTH GILBERT, M.D., F.A.P.H.A., (*Life Member*), AND  
MARION B. COLEMAN

*Division of Laboratories and Research, New York State  
Department of Health, Albany, N. Y.*

THE apparent limitation of tularemia to certain sections of the United States is surprising in view of the great variety of animals and birds which have been shown to be susceptible to this disease. So far as can be determined, only 12 cases, enumerated in Table I, are known to have occurred in New York State, and 10 of them were attributed to the handling of rabbits either known or thought to have been imported from other states. In but 1 instance (case No. 3) was a wild animal in this state, a deer, indicated as the source of the incitant. Since no reference has been found in the literature to this species having been infected with *B. tularensis*, a brief history may be of interest.

The patient, a man, frequently butchered and skinned animals, especially during the hunting season. He handled the carcasses of raccoons and hogs 2 days after the first symptoms developed, but the information obtained indicated that there had been no opportunity for infection from these or other animals for a considerable time prior to his illness. On November 8, 1930, during a hunting trip, he injured his left index finger while handling his rifle. Later that day, he dressed a deer which he had shot, and, on November 10, skinned the animal.

On November 13 and 14, he complained of feeling ill and thought he had "grippe." Congestion and pus formation were noted at the site of the wound on his finger. Dr. A. L. Hayes of Willsboro, N. Y., the local health officer, was consulted about 3 weeks after the injury occurred. At that time, in addition to the lesion on the finger, which still persisted, a painful gland, approximately the size of a pigeon's egg, was noted in the left axilla. A clinical diagnosis of tularemia was made, and a specimen of blood, sent to this laboratory on December 2, agglutinated *B. tularensis* in a 1:320 dilution.

<sup>\*</sup> Read before the Central New York Branch, Society of American Bacteriologists, Syracuse, N. Y., June 24, 1932.

When the patient was visited on December 6 by Dr. Schleifstein, a member of the laboratory staff, his condition had markedly improved; the swelling in the gland had subsided, and the lesion on the finger was nearly healed. Washings of the ulcer in salt solution, however, were injected subcutaneously into 2 guinea pigs and some of the material was rubbed on to the abraded skin of 2 others. One of the animals inoculated subcutaneously died within 5 days. Only hemolytic streptococci developed in the cultures prepared at autopsy. Upon histological examination, however, even though streptococci were present, lesions characteristic of tularemia were found. An emulsion of the spleen was rubbed on to the abraded skin of 2 other guinea pigs, and a third was inoculated subcutaneously. These 3 animals died within from 5 to 7 days. Gross lesions typical of tularemia were noted at autopsy and *B. tularensis* was isolated from cultures prepared from the spleen.

The 12th case (No. 8 in Table I) occurred as the result of a laboratory accident. During the autopsy of a guinea pig infected with *B. tularensis*, a member of the staff broke a glass-headed push pin which pierced his finger through his rubber glove. Six days later, he became ill. The general symptoms reported were fever, chills, gen-

TABLE I

CASES OF TULAREMIA REPORTED IN NEW YORK STATE FROM JANUARY 1, 1927, TO MARCH 1, 1932

Case No.	Year	Patient's occupation	Probable source of infection	Reported by
1	1927	Club steward	Rabbits purchased for food	Murphy, J. A., <sup>1, 2</sup> Buffalo New York State Health Dept. <sup>2</sup>
2	1928	Housewife	Rabbits purchased for food	New York City Health Dept. <sup>4</sup>

\* These patients handled rabbits in the same market

eral malaise, profuse sweating, weakness, and intense occipital headache. The temperature fluctuated from 100 to 104° C. and returned to normal by lysis 23 days after onset. No local manifestations at the site of infection, nor involvement of the regional lymph glands were observed at any time. Blood collected on the 4th day of illness failed to agglutinate *B. tularensis*, but serum obtained on the 10th and 21st days agglutinated this microorganism definitely in 1:20 and 1:640 dilutions, respectively.

Opportunities to study the agglutination reaction of *B. abortus* in serums from patients having tularemia have been limited. Serums from only 5 of the cases which are known to have occurred in this state were tested in our laboratory, 2 being those just described. That from case No. 3, which agglutinated *B. tularensis* in a 1:320 dilution, agglutinated *B. abortus* in a 1:80 dilution. The others gave reactions with *B. tularensis* in dilutions of 1:80, 1:320, 1:640, and 1:2,500, respectively, but failed to agglutinate *B. abortus* in a 1:10 or higher dilution. Francis<sup>16</sup> states that he obtained agglutination of *B. abortus* with 129, or 22 per cent, of 570 serums from patients having tularemia. In only 12 instances, however, did these reactions approximate the degree of those obtained with *B. tularensis*.

In order to secure information in regard to the occurrence of unrecognized cases of tularemia in New York State, the testing with *B. tularensis* of blood submitted for other serological examinations was undertaken as a routine procedure in 1928. The specimens selected were those which were accompanied by a history suggestive of a febrile disease or which reacted in a presumptive test with *B. abortus*. This study has also furnished further data relative to the incidence of agglutination reactions with *B. tularensis* in serums from cases of undulant fever. Francis,<sup>16</sup> who has examined specimens from various parts of the country, in many sections of which tularemia is fairly prevalent, reports agglutination of this microorganism by 31, or 33 per cent, of 93 serums from patients having undulant fever.

Among over 5,000 serums tested in our laboratory with both *B. abortus* and *B. tularensis*, exclusive of those from the 5 cases of tularemia already discussed, approximately 800 gave agglutination with *B. abortus*, while only 19, from 16 patients, reacted with *B. tularensis* in a 1:80 or higher dilution. Ten of these 16 patients had symptoms of undulant fever and their serums gave agglutination with *B. abortus* in appreciably higher dilutions than with *B. tularensis*. No clinical history of tularemia or undulant fever could be elicited in the other 6 cases. Four of the serums from these patients reacted with *B. tularensis* in higher dilutions than with *B. abortus*, the 5th had a

higher titer with the latter antigen and the 6th agglutinated both microorganisms in a 1:80 dilution. A comparison of the reactions with the 2 antigens is presented in Chart I.

Nonspecific agglutination reactions with *B. tularensis* in serums from patients in New York State having undulant fever—at least with the antigens used in this study—would seem to be almost negligible. As the serums of persons who have had tularemia are believed to retain agglutinative properties for many years, if not permanently, the small percentage of reactions obtained tends to confirm the opinion based on clinical observations, that the disease is extremely rare in this state.

# Serology of Syphilis from the Standpoint of the Public Health Laboratory\*

With Special Reference to Precipitation Methods

JOHN A. KOLMER, M.D., DR.P.H., SC.D., LL.D.

*Professor of Medicine, Temple University School of Medicine; Head of the  
Department of Pathology and Bacteriology in the Research  
Institute of Cutaneous Medicine, Philadelphia, Pa.*

FOR various reasons the choice of a method or methods for the serological diagnosis of syphilis continues to be a problem of prime importance in public health laboratories.

In the first place, there can be no denial of the widespread prevalence of the disease, especially in the larger cities and towns, and the fact that it is one of great importance from the standpoint of public health and economics.

In the second place, it is generally admitted that laboratory examinations continue to be the chief means of diagnosis at the command of the large majority of practitioners of medicine. For the relatively few expert syphilologists, clinical training and experience in diagnosis and treatment reduce the demand and necessity for laboratory aids, but even under these circumstances everyone skilled in syphilology must admit that in the diagnosis of concealed or so-called latent syphilis and as a guide in treatment, the serological tests are indispensable. Certainly the history alone of not a few victims of the disease may be notoriously misleading and in the latent or concealed stages coincident with good general health its detection by clinical methods alone may readily escape the most expert. No one can even calculate with reasonable accuracy the incidence of unsuspected syphilis, and for the detection of these the various serological tests have played and must continue to play a very important rôle.

It is sometimes stated that the diagnosis of syphilis should never be made in the laboratory; on the contrary it is easily proved that in

---

\* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 15, 1932.

not a few instances the diagnosis of primary or acute and chronic syphilis can be made only in the laboratory. I may state therefore on the basis of both clinical and serological experience, that the laboratory tests for syphilis must continue to play a very important part in both diagnosis and treatment with the great majority of both general practitioners and specialists in medicine and surgery.

In the third place, relatively few public health laboratories enjoy the privilege of close contact with experts or clinics devoted to syphilology for checking the results of their serological work. This places upon them an added responsibility and necessity for the most accurate work with special reference to a choice of method or methods to be employed. Furthermore, the great majority of reports are sent to general practitioners who under the circumstances must accept the results and give them great weight in arriving at diagnosis and arranging therapeutic programs. A mistake in serology in either a positive or negative way may be of no great consequence to the expert syphilologist but to the less experienced physician it may be and usually is a serious matter sometimes associated with tragic consequences. I repeat therefore that all serologists and laboratories engaged in the serum diagnosis of syphilis assume a great responsibility, but in none is this responsibility quite so heavy as in the case of the public health laboratory and especially as it represents the hope and only means at the command of a large number of physicians for the aid so urgently required in the diagnosis of syphilis among indigent individuals and those who cannot afford the services of the specialist.

Of importance to all laboratories, but more especially in the case of public health laboratories without any detailed information concerning the clinical status of patients, is the question of the specificity of the serum reactions for syphilis with particular reference to weakly positive and unexpectedly positive reactions. During the active stages of syphilis with large amounts of antibody in the blood, most any of the numerous serological tests are apt to yield positive reactions and present no difficulties in diagnosis; but in concealed and unsuspected or doubtful cases the serum tests should possess above everything else a reliable practical specificity for syphilis so that proper reliance may be placed upon all positive reactions including those that are but weakly and unexpectedly positive. Under these circumstances it is proper to place the burden of proof on the clinician rather than on the serologist when the question of diagnosis is raised or disputed, and require the former to prove that syphilis is absent rather than to require the latter to prove that it is present or to seek various technical reasons and excuses for the positive reports.

Every experienced serologist knows that both complement-fixation and precipitation procedures may be made too sensitive with the risk of securing nonspecific or falsely positive reactions with the sera of non-syphilitic individuals. Personally I would much rather run the risk of securing an occasional falsely negative reaction than a single falsely positive one, and I think this attitude and practice is especially befitting the public health laboratory without the benefit of close contact with the expert syphilologist for the final evaluation of disputed results. What is particularly needed by all laboratories and especially the public health laboratory, is a test or tests possessing the maximum of specificity consistent with sensitiveness in order to earn the confidence of the medical profession in the significance of positive reactions and the great risk of error and responsibility involved in ignoring weakly positive reactions if they happen to be unexpected or out of harmony with preconceived clinical diagnosis.

As stated, the test or tests employed for the serum diagnosis of syphilis should possess the maximum of sensitiveness consistent with specificity because in the majority of instances it is in the concealed or doubtful case or treated case of syphilis with but small amounts of antibody in the blood that the aid of serum diagnosis is most urgently required.

In other words, while complement-fixation and precipitation tests serve a useful purpose in confirming the clinical diagnosis of syphilis, yet there can be no denial of the fact that they should be made especially valuable and available for the diagnosis of unsuspected or concealed cases when diagnosis is difficult or impossible by other means.

Furthermore, the maximum of sensitiveness consistent with specificity is required when serum tests are employed as guides in the amount and kind of treatment to employ. To the best of my knowledge syphilitic infection is to be regarded as present as long as reliable tests yield truly positive reactions. In some cases it may not be possible or even desirable to administer sufficient treatment to secure permanent negativity on the part of serum reactions, but yet it is to be realized under these conditions that infection persists and to take the necessary *therapeutic measures and precautions which are beyond the scope of the present discussion.*

Indeed it would appear that syphilis is not being over-treated; rather it is to be feared that in many cases it is being under-treated and the public health laboratory can do a great deal in the prevention of this very regrettable error by employing a test or tests possessing the maximum of sensitiveness consistent with specificity and encouraging their use as serological guides in treatment.

With the large number of modifications of the Wassermann and the various precipitation tests now being advocated, I can well understand the perplexity experienced by public health laboratories in the choice of method or methods to be employed.

In some instances and especially during the present difficult financial conditions, a decision may be based more upon the necessity of exercising the strictest economy than upon scientific truth or the best service. This is right and proper if not pushed to the extent of seriously involving the questions of specificity and sensitiveness. Personally I believe that it is better not to employ the serum tests at all, but to rely upon clinical judgment alone in the diagnosis and treatment of syphilis, if the serum tests are lacking in a reasonable degree of accuracy and sensitiveness.

Without doubt the precipitation tests are more economical in materials since a hemolytic system is not required, but they are hardly more economical in time as compared with complement fixation tests and certainly require an equal degree of skill and experience for their conduct. Indeed my experience as a teacher of serology has indicated that physicians and technicians can be more readily trained to do a thoroughly reliable complement-fixation test than any of the precipitation tests with which I am familiar, and especially when it involves the matter of reading doubtful or weakly positive reactions. There can be no doubt about the importance of the latter; that is to say, a serum containing large amounts of antibody and yielding strongly positive reactions and one containing no antibody at all and yielding completely negative reactions offer no difficulties in reading and interpretation, but those containing small amounts of antibody and yielding weakly positive or doubtful reactions are the ones presenting most difficulty and are most subject to error and at the same time likely to be of most clinical importance and most urgently requiring the diagnostic aid of serum tests.

In many instances those interested in the precipitation tests have sought to produce one equal in sensitiveness to the Wassermann test, but with few exceptions have not taken the trouble to employ the better modifications of the Wassermann in making their comparative tests. Without doubt some of the better precipitation tests are more sensitive than the original Wassermann reaction and some of its modifications but this is not necessarily true when the complement-fixation test is conducted with a proper antigen and a prolonged primary incubation at a low temperature in the refrigerator.

It may be that circumstances compel the adoption of a precipitation test alone for the serum diagnosis of syphilis, but I believe that

a careful and impartial review of the situation amply confirms the prevalent opinion that the serum diagnosis of syphilis is still best served by employing both a complement-fixation and a precipitation method possessing the maximum of sensitiveness consistent with specificity. And if only one test can be done I believe that a complement-fixation test employing heated serum, a sensitive antigen, and an over-night primary incubation at 6 to 8° C. is still capable of yielding the more reliable reactions in the long run.

It is not within the province of this paper to discuss the mechanism of complement-fixation and precipitation reactions in syphilis with special reference to whether or not one or two kinds of antibody are involved, but certainly experience has shown that neither alone will detect as many cases of syphilis as the two together applied to each serum and that neither alone will exclude syphilis with as much accuracy as when both yield negative reactions. Indeed, during the past several years rather strenuous efforts have been made to displace the Wassermann test altogether in the serum diagnosis of syphilis by showing that this or that precipitation test is equal or superior in sensitiveness and specificity. But as previously stated a great deal of this work has been done with little regard for the kind of complement-fixation technic employed and the whole dismissed by employing a "Wassermann test" which may or may not have been acceptable and usually not employing a modification embracing a proper antigen of acceptable sensitiveness along with cold primary incubation.

I believe therefore that those public health laboratories aiming to give the maximum of service in the serological diagnosis of syphilis cannot escape at present the necessity of conducting a reliable modification of the Wassermann reaction possessing the maximum of sensitiveness consistent with specificity along with at least one of the more reliable of the large number of precipitation tests described from time to time during the past 25 years.

When both yield positive and when both yield negative reactions the evidence is much better and the results are more confidently reported upon than when but one test is employed. But the great difficulty is how to report and interpret the results when one test yields a positive and the second a negative reaction. And this difficulty is particularly apparent in public health laboratories far removed from personal contact with the physician and patient, and more especially when the former is not in position to give an expert and reliable clinical opinion for arriving at the best conclusion in relation to the welfare of the patient.

Fortunately the majority of reactions agree in so far as positive

or negative are concerned but a certain and inevitable percentage of disagreeing reactions can prove very disturbing. Under these circumstances one may surmise that the use of two precipitation procedures instead of one precipitation and one complement-fixation test may give greater uniformity in results and solve the difficulty while being more economical in that a hemolytic system is not required; but my experience with the Meinicke, Kahn and Kline precipitation tests indicates that this is not a solution at all, as these tests applied to the same sera give a higher percentage of disagreeing reactions than any one or two of the three employed along with my own modification of the Wassermann reaction.

Of course, an easy solution of this problem is to employ only one test on the assumption that if it is properly chosen and conducted the reactions will be accurate in at least 90 per cent of sera. Under these circumstances the choice must be a matter of individual preference and decision. Personally I prefer the quantitative complement-fixation test with a superior antigen and cold primary incubation as possessing an acceptable degree of sensitiveness, a higher practical specificity and a greater ease and accuracy in the reading of weakly positive reactions than any of the precipitation tests with which I am familiar.

But my custom during the past 7 years has been to use at least one precipitation test along with my own modification of the Wassermann test as better serving the purposes of serum diagnosis. My clinical experience in the diagnosis and treatment of syphilis invariably suffices for reaching a decision in private practice when the reactions are positive with one and negative with the other, and since a certain percentage of these disagreeing reactions is inevitable, I see no escape from the conclusion that public health and other laboratories seeking to render the best possible serum diagnosis of syphilis must employ both a complement-fixation and a precipitation test and leave the final decision up to the physician when the reactions disagree.

In this connection I may state, however, that differences in the degree of positiveness should not be allowed to be a disturbing factor. A strongly positive Wassermann reaction may occur with a weakly positive precipitation reaction or the reverse. The only thing that really counts is specificity or the reliability of the positive reactions without regard to the degree which is so largely at the mercy of technical factors. Furthermore there can never be a strict correlation between the degree of positiveness of either complement-fixation and precipitation tests and the clinical status of the individual patient since symptoms largely depend upon the physiological importance of the

tissues infected while the degree of positiveness largely depends upon the degree of spirochetic activity. For example, a case of locomotor ataxia may present pronounced signs and symptoms with but weakly positive reactions, whereas a case of concealed syphilis with a heavy infection involving an organ or tissue of lesser importance may be in excellent general health with strongly positive reactions.

In so far as a choice of precipitation tests is concerned from among the large number described by Sachs and Georgi, Dreyer, Vernes, Meinicke, Kahn, Hinton, Kline, and others are concerned, my own experience has been limited so far to those of Meinicke, Kahn and Kline, with special reference to the Kahn test, which I have been employing routinely as a control on my modification of the Wassermann test during the past 7 years.

I am particularly well impressed, however, with the new or more recent modification of the Meinicke generally designated as the "clarification reaction." In a comparative study made about 3 years ago by Dr. Elizabeth Yagle and myself we found that the reactions were more definite and easier to read and interpret than the reactions of the Kahn test. Furthermore the new Meinicke was more sensitive while possessing an equal degree of specificity.

For example, in 90 carefully chosen cases of syphilis the Meinicke test yielded 77, or 85 per cent, positive reactions, whereas the Kahn gave 56, or 73 per cent, positive reactions. With the sera of 62 non-syphilitic controls both tests yielded 4, or about 5 per cent, nonspecific or falsely positive reactions.

During the past year, however, I have been particularly interested in the Kline microscopic test and have had Dr. P. Menlowe, one of my graduate students, make a particularly careful comparative study of it with the Kahn and my modification of the Wassermann test, which were conducted separately and independently by Miss C. Richter. Dr. Menlowe had the advantage of some training under Dr. Kline and used the apparatus and antigen kindly furnished by him. The tests were done and the reactions recorded with no knowledge of the clinical diagnoses or the results of the Kahn and Kolmer reactions.

With the sera of 100 cases furnished from my own practice the reactions of all three tests agreed in 91 per cent and disagreed in 9 per cent of sera. In the case of the disagreements the results have been summarized by Dr. Menlowe as follows:

	<i>Kline</i>	<i>Kahn</i>	<i>Kolmer</i>
True positive reactions:	3%	4%	6%
Falsely positive reactions:	2%	1%	0
True negative reactions:	1%	2%	3%
Falsely negative reactions:	3%	3%	0

With the sera of 1,000 additional cases drawn from the hospital and out-patient clinics of the Graduate Hospital of the University of Pennsylvania with special reference to the clinic for dermatology and syphilology of Dr. Jay F. Schamberg, the results were as follows:

In 86.7 per cent of sera the reactions of all three tests agreed in so far as positive and negative were concerned while in 13.3 per cent they disagreed.

An analysis of the latter showed the following:

	<i>Kline</i>	<i>Kahn</i>	<i>Kolmer</i>
True positive reactions:	8.7%	6.6%	7.0%
Falsely positive reactions:	1.5%	1.4%	0
True negative reactions:	1.1%	1.2%	2.4%
Falsely negative reactions:	2.0%	4.1%	3.9%

In general terms the Kline microscopic precipitation test was definitely more sensitive than the Kahn test and slightly more sensitive than the Kolmer modification of the Wassermann test. On the other hand, however, the Kline also gave more nonspecific or falsely positive reactions than the Kahn, whereas the complement-fixation test did not give any falsely positive reactions.

It would appear therefore that the Kline test is somewhat too sensitive in its present state. Certainly it is more sensitive than my modification of the Wassermann reaction but, as previously stated, I prefer to lose a bit in sensitiveness if necessary in order to preserve intact the more important question of specificity.

This is also borne out by the results observed with the sera of controls. For example, tests conducted with the sera of 35 physicians and technicians of the laboratory staff, among whom the question of syphilis could be excluded with more than usual accuracy, the Kline test gave a weak falsely positive reaction with 1 while the Kahn and Kolmer reactions were completely negative with all.

With the sera of 25 cases of acute scarlet fever, the Kline gave apparently falsely positive reactions with 6, the Kahn with 1, while the Kolmer reaction was completely negative with all.

With the sera of 21 tuberculous women among whom it was believed that syphilis could be definitely excluded, the Kline gave 4 and the Kahn 3 apparently falsely positive reactions while the Kolmer-Wassermanns were negative with all. With the sera of 4 tuberculous women believed clinically to be syphilitic, the Kline and Kahn tests gave positive reactions with all while the Kolmer-Wassermann was positive with 3.

With the sera of a group of 17 diabetics believed to be free of syphilis, the reactions of all three tests were completely negative.

In so far as a choice between the Meinicke, Kahn and Kline precipitation procedures is concerned, I believe therefore that the new Meinicke clarification test is worthy of very serious consideration. If the Kline is employed it is almost certain to yield more sensitive reactions but with the drawback of being oversensitive with the consequent danger of yielding more falsely positive reactions. Much to my regret I am not able at present to express an opinion of the Hinton and Eagle tests, which I understand are well spoken of in some localities.

Certainly it would appear advisable at present to use at least one of these precipitation tests along with a Wassermann test of proven sensitiveness and specificity. The advantage of this practice is much better appreciated in individual cases than reflected in figures and percentages, as I well know from being in the unusual position of being actively engaged in both clinical syphilology and serology. While I appreciate that strenuous efforts have been and are being made completely to displace the Wassermann test, yet I am absolutely certain that this is not possible or advisable and that public health and other laboratories can best serve the serology of syphilis by employing the Wassermann along with at least one precipitation test.

#### SUMMARY

1. A choice of method or methods for the serum diagnosis of syphilis is a problem of special interest to public health laboratories.

2. Of particular importance to all laboratories and especially those engaged in public health work without the advantage of skilful clinical checking of reactions is the question of the specificity of weakly and unexpectedly positive reactions.

3. What is particularly required is the use of a test or tests possessing only the maximum of sensitiveness consistent with specificity in order to earn the confidence of the medical profession in the significance of weakly positive reactions.

4. By employing a test or tests possessing the maximum of sensitiveness consistent with specificity, public health laboratories can do a great deal in minimizing the regrettable error of insufficient treatment of syphilis.

5. Precipitation tests for syphilis are more economical than the Wassermann test since a hemolytic system is not required but they demand an equal degree of skill and one more subject to error and interpretation of weakly positive and doubtful reactions.

6. Not infrequently the various precipitation tests for syphilis have been compared with complement-fixation tests lacking in acceptable sensitiveness and specificity and consequently resulting in erroneous conclusions.

7. Despite strenuous efforts none of the precipitation tests can be said to have displaced complement-fixation tests possessing an acceptable degree of sensitiveness and specificity when judged impartially and scientifically with adequate clinical control. The use of two or more precipitation procedures has not proved as satisfactory as complement-fixation and precipitation tests of acceptable sensitiveness and specificity for the routine testing of sera.

8. It is impossible at present to make a choice of a single precipitation test from among the large number available.

9. The new Meinicke or "clarification" test has been found more sensitive than the Kahn test, of equal specificity and easier to read and interpret the reactions.

10. In a comparative study of the Kline microscopic and Kahn precipitation tests and the Kolmer modification of the Wassermann test, the reactions agreed in 86.7 per cent of over 1,000 sera and disagreed in 13.3 per cent.

11. In general terms the Kline microscope test was more sensitive than the Kahn and Kolmer tests but likewise gave a higher percentage of nonspecific or falsely positive reactions than the Kahn test while the Kolmer modification of the Wassermann test gave no falsely positive reactions.

12. At the present time the serum diagnosis of syphilis is best served by conducting a carefully chosen complement-fixation and precipitation test on each serum.

NOTE: Since the writing of this paper an excellent article by Dr. Lucy S. Heathman and Miss Margaret Higgenbotham on A Study of the Kolmer-Wassermann, Kahn and Kline Tests has appeared in the *American Journal of Syphilis*, 16:385, 1932. The authors concluded that the Kolmer and Kline tests appeared to be a more valuable combination than the Kolmer and Kahn, or the Kahn and Kline as tests for evidence of syphilitic infection. They also found that the Kolmer and Kline gave more positive reactions in congenital syphilis than did the Kahn test. These investigators likewise found that the Kline test, being more sensitive than the Kolmer and Kahn, also gave more positive reactions in cases considered to be non-syphilitic. If any public health laboratory adopts the principle that two tests should be carried out on the principle of employing one with a high degree of sensitiveness but less specificity and another with less sensitiveness but higher specificity, I agree with the authors that the Kline better serves the former and the Kolmer the latter purpose.

---

## Courses on Maternal Hygiene in Italy

A DECREE of April 8, 1932, issued by the director of the National Bureau of Maternal and Child Welfare, provides for the establishment in all the universities of Italy of 1-month summer courses in prenatal and postnatal hygiene for the physicians assisting the directors of the various health centers and engaged in the teaching of hygiene to the mothers and children attending the centers. Similar courses are also to be established for those midwives who are employed by the health centers as health visitors in rural districts. These courses will be given under the supervision of the previously mentioned bureau.

Another decree orders that a special inspection of all infant asylums and receiving homes in Italy be made in May, 1932. A professor of pediatrics was appointed in each province to carry out the inspection. This special inspection is to be made in addition to the inspections that the National Bureau of Maternal and Child Welfare has been making at irregular intervals.

A circular was also issued by this bureau to its branches throughout the country prescribing the technic of air bathing, sea bathing, and sun bathing, giving a classification of cases for which the seashore, the mountains, or level country is advisable.—*Maternità ed Infanzia*, Rome, Apr., 1932.

# An Appraisal Form for Industrial Health Service\*

LEVERETT D. BRISTOL, M.D., DR.P.H., F.A.P.H.A.

*Health Director, American Telephone and Telegraph Company,  
New York, N. Y.*

WITH reference to the importance of health in industry, the late Thomas Edison, dean of American inventors and father of several world-wide industries, said:

Coming generations of inventors will do their pioneering in the field of health. Electric light, telephone, radio, talking picture, automobile, air-plane—these things we have. What we have not is control over our own lives and bodies comparable to our control over material things. . . . Sickness is pretty hard on the workman. . . . There is too much sickness. . . . Something will have to be done about it.

It is significant that many industrial organizations have set themselves to the task of doing something about health promotion and disease prevention among employees. Some companies, fully realizing the direct relation between health and efficiency of workers, already are engaged in many of the activities which might be suggested in an Appraisal Form, while others have yet to develop a well rounded health program; for the former an appraisal will be the means of satisfactory audit; for the latter, it will lay the groundwork for a more complete program in the future.

One industrial group already has gone on record as favoring the adoption of some means of rating the health activities of comparable units of its company as a most effective means of creating and sustaining interest, and suggests the formulation of a plan which would properly evaluate the constructive elements of a reasonable health program in industry. The writer has prepared an initial Health Appraisal Form which is an attempt to take the first steps in the development of such a plan. It is conceivable that it might be broadened to include all personnel and industrial relations activities if subsequently desirable, or abbreviated to cover only such activities as those of medical departments. A suggested outline of an Appraisal

\* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.  
Complete, detailed Form filed with the Chairman of the Committee on Administrative Practice, A.P.H.A.

Form for Personnel and Industrial Relations Service in general is given as an Appendix of the Form together with a Health Appraisal Form for smaller companies.

The Industrial Health Appraisal Form has been developed on the assumption that prevention and health protection, rather than curative medical treatment of accidents and industrial diseases, should dominate an industrial health service. In other words, industrial hygiene should include vastly more than emergency medical attention to specific occupational diseases, poisonings and accidents.

An Appraisal Form for Industrial Health Service does not mean to imply that all the suggested practices covered therein necessarily are desirable or feasible at this time in all organizations. The questions cover most of those things which might be included in a complete program for the larger companies. It is for the future to determine what should and can be done to meet local conditions and needs, especially of the smaller business concerns. This latter may be worked out best through local coördinating and assisting community agencies, such as state or local health or labor departments or associations.

#### THE NEED FOR MEASUREMENT OF INDUSTRIAL HEALTH SERVICE

The most important requirement at the present time for the further development and administration of industrial health programs is a plan or method for the measurement or appraisal of health activities. Such a plan would serve not only to evaluate but actually to promote industrial health services. While some industrial organizations have well organized health programs, much remains to be done by other companies in the development of a complete program.

There are so many factors entering into the problem of sickness, some of which are intangible and not, as yet, even remotely controllable, that it is difficult (if not impossible and wholly unfair) to judge the results of health administration or supervision, particularly in the industrial field, in terms of sickness rates alone or the amount of lost time due to sickness. The methods used in measuring the results of first aid and safety work are not well adapted to the appraisal of a health program.

In a positive health conservation program it is *performance or effort* in the development and administration of health activities (which taken as a whole eventually will result in reduced sickness) that should count, rather than the immediate decrease of sickness and time lost from work. The measurement of health work carried

on by an industry or by a particular area, division, district, or department in a company, should take into account the degree to which the company, or any unit of the company, has taken the necessary steps to protect and advance the health of employees.

The measurement of an industrial health program from the viewpoint of *total performance or company effort* presupposes and suggests the development of a so-called "Appraisal Form," "Rating Schedule," or "Record Booklet." The National Board of Fire Underwriters has developed such a form to assist cities in rating their fire protection services, and the American Public Health Association, American Child Health Association, and other public and community agencies have prepared forms to be used by states, cities, and counties in appraising their public health services. There is no apparent reason why such a practice and form should not be attempted by private and semi-public *industrial* organizations and their various departments and geographic divisions.

In the development of our preliminary and tentative form for industrial health appraisal, free use has been made of the experience, suggestions and published material of the above mentioned agencies, particularly of the National Board of Fire Underwriters and of the American Public Health Association, to which acknowledgment is made. Some of the major activities, standards, criteria and values in this industrial form have been set down tentatively and rather arbitrarily on the basis of those developed for the appraisal of city health work and of rural health work by the Committee on Administrative Practice of the American Public Health Association, on the assumption that industrial groups are nothing more than special working units of a community; and that industrial organizations, so far as possible, should fulfil their own share of obligations and responsibilities for community health and welfare.

#### A. OBJECTIVES

The objectives sought in the development of an Appraisal Form for Industrial Health Service are:

1. To obtain a picture of the extent or degree of organization and development of modern industrial health practice in a company or any unit of the same.
2. To serve as an instrument to promote, guide, interpret and measure health work in an industry or any of its units.
3. To arouse interest on the part of all company officials in the need for adequate health service in the industry; and to present those more directly in charge of the management of any unit with a tangible and concrete form of objective.

4. To provide stimulus for the development of a well balanced industrial health program, and to supply standard indices by which progress in health work may be followed by company personnel.

The purpose of such a measuring device at the moment is not to determine the quality or ultimate effectiveness of industrial health activities, but rather to show the extent and quantity of such work and to serve as an objective measurement to be used by personnel representatives, health supervisors, and other officials of business concerns in the inspection, appraisal or scoring of their own health activities, and the comparison and checking of the same from year to year. Indirectly, quality of work also would be measured to a considerable degree.

While such a rating schedule as suggested may be used in fostering the competitive spirit in health matters between various comparable units in a company, the chief use of such an Appraisal Form in the immediate future would be as a basis for comparison between what is and what should be in any given company or unit.

#### B. STANDARDS

It should be fully understood that the various criteria, standards and values used must be revised from time to time as conditions and practices change; but such changes should not be too rapid nor radical; otherwise it will become difficult to compare progress from year to year.

In general, the standards adopted for this Appraisal Form are far from being ideal, but have been set as high as practicable. The Form is in the nature of a scoring booklet and contains numerical values assigned to various activities in the industrial health promotion field. The rating for each activity is based partly on the health promotional value of each item in question, but more especially on the need for further development in industry of the particular activities noted.

#### C. CONTENTS OF FORM

The Form consists of various sections and subdivisions with their assigned values, as shown in Table I.

In the Form itself, not possible in this condensed paper, each of the subdivisions is further divided into various items or criteria which measure the amount of performance or frequency of practice, both of which are adapted to rather strict, impersonal quantitative measurement and can be assigned a definite quantitative number and value. To a lesser extent some of the activities are standard procedures

which cannot be scored down; they either are or are not routinely performed and can have only a fixed number and value and given a full score or nothing. To arrive at a total score for a company, or any unit being appraised, the major section totals are added after

each one of the sub-items has been determined and added. At the end of the Form has been included an "Appraisal Summary" item by item, covering section and grand totals to be used for final scoring. More detailed instructions will be found in the Form itself under "General Directions for Use of the Industrial Health Appraisal Form."

As Appendices there are included a proposed brief Form for the use of smaller industries or business concerns, its contents being outlined in Table II; and a suggested Form for Personnel and Industrial Relations Service in general, outlined in Table III of this paper.

### SURVEY QUESTIONNAIRE

Combined with the Appraisal Form is a suitable schedule or questionnaire for obtaining in proper sequence the fundamental data necessary and required for an intelligent appraisal of company health work. Thus the left-hand pages of the Form are given over to the so-called "Survey" containing questions and precise information in order that definite scoring can be made. On the right-hand pages

the "Appraisal Form" itself is given, opposite the corresponding items in the "Survey Schedule," showing the standard values for the various items and containing columns for putting down the assigned scores. If it is desired not to use the right-hand page appraisal sheets, the left-hand pages may serve at least as an outline of a well rounded program.

#### D. COLLECTION OF DATA

It is assumed that it probably will take considerable time for Personnel Representatives or other officials of industrial companies to fill out the suggested Form, at least for the first time. Much of the information called for may never have been brought together under one head, by one department or person. Reference to and assistance from various departments and officials in a company may be required before the data can be assembled completely. When once the information and material have been brought together in concise form, and the "machinery" set up for gathering similar data from year to year, the task of periodic appraisal of company health activities and facilities should be fairly brief and simple.

#### PRELIMINARY TRIALS AND OPINIONS OF FORM

This survey and appraisal form has been used by one state-wide industrial organization, of about 4,000 employees, on a preliminary trial basis, and the vice-president in charge of personnel and public relations of this company makes the following comment:

I like the plan immensely. It advances our health program and medical supervision very materially. In giving us a chart to guide this activity, we can plan our work with confidence and definiteness, confining our major effort into administration.

The personnel officer of another company employing about 10,000 men and women scattered over several states, says:

I hope it will not be long before such a Form is officially adopted and published, because I feel there is a real need for it and that it will be most helpful in crystallizing management's views of the relative importance of various health activities. Also, it will be helpful to those of us who are undertaking to initiate and direct such activities, in measuring and comparing results by departments or areas.

#### PUBLICATION OF TENTATIVE FORM

Based on his past experience as a county health officer, and as a state health officer, as well as his active participation in city health administration, the writer is thoroughly convinced of the value of the

appraisal method not only in such public units as states, cities and counties, but also in semi-public and private industrial units; and he desires at this time to present this Appraisal Form in its preliminary and tentative state of development to the American Public Health Association with the suggestions: (1) that it be referred to the Committee on Administrative Practice, and with the tentative approval of the committee that it be published as a preliminary draft, for study and experimental use; and (2) that a new sub-committee on the Appraisal of Industrial Health Service of the Committee on Administrative Practice be appointed to follow and study the experimental use of the Form and possibly later, with the advice of other available experts in the field, to revise, standardize and adopt this or some similar Form. In view of the fact that such a Form would be particularly adapted to the use of large industries, an abbreviated Form, as outlined in Table II, also has been prepared for the experimental use of smaller companies and business concerns and might well be included as an appendix of the larger Form when published.

## CONSULTING AND ADVISORY SERVICES FOR SURVEYS AND APPRAISALS

The suggestion also is made that if and when such a Form is available, the American Public Health Association might supply to large and small industries, on request, a consulting and advisory service on the Appraisal of Industrial Health Service, as has been done for the appraisal of health service in such public units as cities and counties. Such a consulting and advisory service ultimately might pay for itself through the stimulation of industrial group memberships in the American Public Health Association, which could offer and be made to cover these technical advisory services on industrial health appraisal.

## COÖPERATION OF OTHER ASSOCIATIONS

Finally, in so far as the standardization and adoption of an Industrial Health Appraisal Form (with its special emphasis on sickness and accident prevention and health promotion) involve the technic of medical and surgical examination or treatment, it would be desirable for the American Public Health Association to seek the assistance and advice, if not the active coöperation and participation, of representatives of the American Medical Association, American Surgical Association and the Association of Industrial Physicians and Surgeons. Moreover, the coöperation of some such organization as the American Management Association, which includes representatives of the leading business concerns of the country, might be obtained to foster the Health Appraisal idea among industries just as the Chamber of Commerce of the United States has stimulated the Appraisal of Health Administration in American municipalities.

## THE SIXTY-FIRST ANNUAL MEETING

THE 61st Annual Meeting of the American Public Health Association has passed into history, but carries with it many pleasant memories for all of those who attended. The number of registered delegates was 1,233. Many people who attended only one or two sessions did not record their presence. Estimating their number on the basis of past experience, and including those actually registered, upwards of 1,600 were in attendance. It is interesting to direct attention to a statement by the convention manager of one of the large Washington hotels. He said the A.P.H.A. meeting was the only convention held in Washington in 18 months the attendance at which realized and exceeded the expectations. Other gatherings have been from thirty-five to fifty per cent below the estimate. The forecast for our meeting was 800 to 1,000, and the final figures are surprising and gratifying, particularly in view of the fact that travel expenditures in health department budgets have been so drastically cut. Many members of the Association travelled to the Annual Meeting at their own expense.

The Committee on Meetings and Publications struck two new notes—first, upwards of 100 new names were included as giving papers in our program, and second, a summary of work from the 10 different Sections was given in the Public Health Ten Star Final. We believe that including new names should add to our membership and increase the interest of old members, although we have on our program always

a number of tried and true stand-bys, particularly on our various committees, who give us the substance of what has been done in their various branches during the year which has elapsed since our last meeting.

The Laboratory Section had by far the greatest number of papers, so much so that it will be impossible for us to give all of them to our readers in the pages of the JOURNAL. Almost every subject of interest to laboratory workers was considered.

At the first General Session, which was largely attended, President Hoover gave a short address. Following this, the President of the Association summed up the situation in the country as regards health, and also the condition of the Association itself. It was an encouraging summary, showing that in spite of the depression, the health of the

*Dr. Dublin, President Hoover, and Dr. Ferrell at the reception on the White House lawn*

country has never been better, but he uttered a very sound warning against being too optimistic, since there is no doubt in the minds of practically all health workers that the effects of the depression, both physical and mental, will show themselves sooner or later.

The Association itself is in a healthy condition. The number of Life Members has been doubled during the year and losses have been made up, so that the membership roll is now at its peak. However, the budget has been hit and all salaries have been reduced. The President paid a deserved tribute to the workers on the cheerful way in which they have accepted the situation, including the pay cuts, and continued their work with the highest degree of enthusiasm and efficiency. There has been no let-down in the morale.

At the Montreal meeting in 1931, it was considered possible to enlarge the JOURNAL by 20 pages a month, which would have taken a tremendous burden off the shoulders of the Committee on Meetings and Publications, and especially the editors. However, instead of the increase, we have during the year lost 64 pages, which has made it necessary to return even papers already prepared for the printer, and for which prompt publication was confidently expected.

We have already said that the program was excellent in all respects and it may seem invidious to pick from it certain sections which seemed to attract especial attention. The first General Session was followed by a reception which was largely attended. On Wednesday morning, a symposium on milks and their especial antirachitic value, their development and use, attracted much attention, not only on account of the recognition of the importance of foods in general and milk in particular, and their discussion in journals, scientific as well as lay, but also on account of the high standing of those who took part. At 12:30 those who desired to do so went to the White House lawn where Mr. Hoover received them and a photograph of the group was made. At 1 o'clock, a special luncheon session on diphtheria prevention was held, which also claimed a very large attendance. At 2:30 one of the new features, the Ten Star Final, was held in the large ballroom. In spite of the fact that 800 chairs had been provided, there were many standing. It was the opinion of those who attended that under one name or another such a summary of the activities of the Association, and of the condition of the sciences dealt with by our 10 sections, should be a feature of future meetings.

Washington was at its loveliest. The local committee had done everything possible for the comfort and enjoyment of the guests. Excursions were provided, free of expense, to the National Institute

of Health, the Surgeon General's Library, Walter Reed Hospital, Sewage Disposal Plant, and many other places of interest. Altogether, the meeting at Washington may be put down as a success which will long be remembered by members of the Association.

## RAW VS. HEATED MILK

STRANGE as it may seem to those of us who have studied the pasteurization question and who believe in it, there is still agitation in favor of raw milk and allegations are made that the heating of milk destroys to a certain extent its nutritive value. There is also an association in the United States devoted to pushing the use of raw milk. Some of its agents are making the claim that pasteurization is injurious.

The report in 1931 from the National Institute for Research in Dairying<sup>1,2</sup> was quite disconcerting, as it apparently showed that, as far as rats were concerned, milk pasteurized at 145–150° F. for ½ hour and milk heated to 210–212° F. for ½ hour gave evidence of a lack of certain nutritive factors as evidenced by reproduction. Animals fed on raw and pasteurized milk, plus biscuit made of white flour and water, grow and reproduce normally, while in those fed on sterilized milk, plus the biscuit, reproduction failed, and of the original rats, many failed to reach maturity. As far as this part of the experiment goes, it demonstrates only injury to the vitamin concerned in reproduction, but the report further states that there were visible differences in the rats even in the first generation, always in favor of raw and to the great disadvantage of sterilized milk. The difference between the effects of pasteurized and sterilized milk in these experiments must be noted, in spite of the general conclusions reached, that heating injured the nutritive value of milk. During 5 years of study, the authors state while animals thrived on milk for a considerable time, never before have they been able to continue feeding beyond the fourth generation on an almost exclusively milk diet.

In view of this situation, the report from the U. S. Public Health Service of a group of workers headed by Leslie C. Frank<sup>3</sup> is reassuring, and of great value in the campaign which is going on everywhere for the pasteurization of market milk. Studies on children fed raw and heated milk plus the supplementary diet received by the average American child between 10 months and 6 years of age have been carried on in 39 cities situated in 10 states. The number of children covered was 3,700, and the general conclusion reached was:

The growth-promoting capacity of heated milk plus the supplementary diet received by the average American child of 10 months to 6 years is not measurably less than the growth-promoting capacity of raw milk plus the supplementary diet received by the average American child of 10 months to 6 years.

Further analysis of the general results shows that there were 32 cases of diphtheria among 1,875 children who received heated milk only against 40 among the 1,762 children fed predominantly on raw milk, case rates of 17.1 and 22.7 per 1,000, respectively. For scarlet fever, the group fed on heated milk showed 43 cases against 73 for the raw milk group, case rates of 23.0 and 41.4 per 1,000, respectively.

Intestinal disturbances reported under such names as diarrhea, dysentery, flux, colitis, and summer complaint, amounted to 426 for the group fed on heated milk against 491 for those fed on raw milk, case rates of 227.0 and 278.0 per 1,000, respectively. Excluding diarrhea, which the authors of the report believe includes many mild cases not caused by milk, the cases of intestinal diseases amount to 208 for those fed on heated milk and 395 for those fed on raw milk, case rates of 111.0 and 196.0 per 1,000. For those fed on heated milk there were 59 cases of rickets against 90 in the raw milk group, case rates of 31.5 and 51.1 per 1,000, respectively. It was found that among those fed on heated milk predominantly, more were given cod liver oil.

The average weight of the children in the two groups differed insignificantly, being 33.6 for the heated milk group and 33.2 for the raw. The same statement applies to average height, being respectively 37.5 and 37.4 inches. The supplementary diet of the 2 groups was very much the same, except for cod liver oil which was given during an average of 41.6 per cent of the lives of children fed heated milk, and only 27.6 per cent of the lives of those fed raw milk. The average weight of 636 children fed on heated milk who received no cod liver oil was 33.5 pounds as compared with 33.8 pounds for 794 children of the same group who received cod liver oil during more than half of their lives, indicating that the percentage of life during which cod liver oil was fed did not affect the relative position of the 2 age-weight curves to any extent. It is apparent also that the children who were fed raw milk predominantly had a higher incidence of diphtheria, scarlet fever, intestinal disturbances, and rickets than those receiving heated milk only.

This report does not consider tuberculosis, but we have evidence from New York City particularly, where 98 per cent of the milk is pasteurized, that the incidence of bovine tuberculosis in children has dropped enormously. This decrease in tuberculosis of human origin

among infants is noted also. In view of these facts, taken with those now presented, the advocates of pasteurization can go ahead with a clear conscience in their work, feeling assured that they are not in any way injuring the health prospects of children, but are, on the other hand, protecting them against tuberculosis, intestinal disorders, and all other diseases which are transmitted through milk.

### IS THE REGISTERED INCREASE OF HEART DISEASE REAL OR APPARENT?

AN interesting and timely paper<sup>1</sup> discusses the alleged "appalling increase" in heart disease. The writers acknowledge that the number of deaths charged to the cardio-arterio-renal system is enormous and constitutes one of the new and important health problems. This opinion will be accepted by all who have studied the question. They point out, however, that in spite of this alleged rapid increase, they know of no extensive or well planned study to determine its causes or to establish control measures. In place of this, there is a good deal of talk about the pace of modern living and other similar phrases which mean little or nothing. As they express it, there is a wealth of opinion but little real scientific evidence. Their own study is devoted entirely to the mortality statistics of New York City. They have analyzed the basic data as given in the death certificates and have pointed out the sources of errors. They point out also—what is well known to all pathologists—that the pathological changes and etiological factors of heart disease are not to be limited to the heart itself, but include also the arteries and kidneys, from which fact the term cardio-arterio-renal system has evolved.

In New York City, the registered increase in heart disease is admitted, but there is shown to be a fairly corresponding decrease in apoplexy, Bright's disease, and deaths from senility. The authors hold that the registered rise in death rate from heart disease is largely, if not wholly, fictitious, and that statistics based on these alone are fallacious, since those assigned to apoplexy, arterial and kidney diseases, and senility must be taken into account. They point out further that for the registration area of the country as well as for New York City, the specific death rates, even in the higher age group, have declined since the beginning of this century, a fact which they find it

hard to reconcile with any considerable increase in the mortality from heart disease.

There seems to be little doubt that the group of diseases classified under cardio-arterio-renal, which often goes under the name of heart disease, is more common now than it was 30 years ago. It is possible that there are changes in the incidence independent of the increased age level of the population, but so far, no one has been able to prove this. Some pathologists hold, apparently justly, that the increase is in part real, giving as possible factors which may be concerned as items under etiology—sex, age, occupation, habits, previous disease, acute or chronic infections, especially of the lungs such as those following influenza, which affected such a large population of the country during the epidemic of that disease which occurred from 1918 to 1923. Further than this, there is a possibility that the inheritance of a poor cardio-arterio-renal system may play some part, but there is no ground for considering this too seriously.

Of real significance must be considered the alcoholic beverages which are now taken. These have long been assigned as a cause of heart-blood-vessel-kidney disease. If it is a fact that alcohol does play such a part in this group of diseases here in America since prohibition came in, we have gone the limit in the use of hootch and other raw alcoholic beverages into which poisonous products, due to rapid distillation, imperfect fermentation, etc., may have passed.

The paper is worthy of the consideration of all interested in preventive medicine and it is to be hoped that the pathologists and the statisticians of the country will join hands in an effort to determine the truth and to propose remedies which may be put into effect by our health authorities.

#### SIR RONALD ROSS

SIR Ronald Ross died on September 16 at his home in Putney, England, at the age of 75 years. He is one of the men who has written his name indelibly in medical annals, owing to his discovery that the *Anopheles* mosquito carries malaria, and of the method by which this is accomplished. Unfortunately, a bitter controversy arose over the credit for this, which we believe belongs practically entirely to Sir Ronald Ross. Those in charge of the awarding of the Nobel Prize in Medicine certainly had the same opinion, as this prize was given to him in 1902 on account of his discovery. The clinching

argument has always been a poem which he wrote on the day his discovery was made: "I know this little thing a myriad men will save." This shows that he realized not only that he had made a discovery, but also what it meant to the world. He had the good fortune to live long enough to see his ideas put into effect and to see malaria brought under control in many parts of the world. There is little question that if malaria was as deadly a disease as yellow fever, the control of it would be more perfect, since abundant funds would be available for the work.

Sir Ronald Ross was born at Almora, India, the son of General Sir Campbell Claye Grant Ross. He obtained his medical education in England and entered the Indian Medical Service in 1881. There is little question that he owed his inspiration to follow the line of work in which he made this great discovery to Sir Patrick Manson. Laveran had discovered the germ of malaria and had even forecast the mosquito conveyance, but did not prove it. Sir Ronald overcame what would have been insuperable difficulties to others. The authorities interrupted his work several times and did not seem to see the value of it, though at the time there were more than a million deaths every year from malaria in India. During the World War he lost his son in one of the early drives. He served as consultant in malaria to the War Office, and later held a similar position in the Ministry of Pensions.

Many honors were paid him and degrees given to him, but pecuniary assistance did not follow to any great extent. He was the founder of the Ross Institute and Hospital for Tropical Diseases, but toward the end of his life was very hard put to it for a living.

He has been described as a "many sided genius." In addition to his scientific work he wrote poetry, novels, and five mathematical works, which his latest biographer, R. L. Megroz, feels have not received sufficient recognition. He had many friends in America.

Few men have made discoveries of more value to the human race, and his name will always be honored by all public health workers as well as all members of the medical profession.

## ASSOCIATION NEWS

### DR. JOHN A. FERRELL, PRESIDENT A.P.H.A.

*John A. Ferrell, M.D.  
President, A.P.H.A.*

**D**URING the past year the office of President of the Association has been filled ably and acceptably by Louis I. Dublin, Ph.D. The year has been a trying one and he has successfully met problems more difficult than most presidents have to face. We will still have his wise counsel as a member of the Executive Board. We are fortunate in his successor, John A. Ferrell, M.D., Director of the International Health Board of the Rockefeller Foundation, who has served in the capacity of President-Elect of the American Public Health Association since the last Annual Meeting in Montreal. His work is well known to sanitarians from the time he joined the Rockefeller Sanitary Commission in 1910. He was first in charge of the Commission's Work in North Carolina directing an educational campaign against hookworm. When the Rockefeller Sanitary Commission became the International Health Board with a world-wide program, Dr. Ferrell was made Director for the United States.

### DR. HAVEN EMERSON, PRESIDENT-ELECT A.P.H.A.

**H**AVEN Emerson, M.D., of New York, President-Elect of the American Public Health Association, received his A.B. degree from Harvard and his medical education from the College of Physicians and Surgeons of Columbia University, graduating in 1899. After 2 years of internship at Bellevue Hospital he entered general practice of medicine in which he con-

tinued for 15 years, during which he was successively demonstrator and associate in Physiology and associate in Physical Diagnosis at the College of Physicians and Surgeons.

In 1914 he was appointed Sanitary Superintendent and Deputy Commissioner of Health to New York City. In 1915 he succeeded Dr. Goldwater as Commissioner of Health. From Janu-

ary, 1918, to June, 1919, as Major, Lieutenant-Colonel, and Colonel in the Medical Corps of the Army, Dr. Emerson held the position of Epidemiologist of the American Expeditionary Forces in France. During 1920 and 1921 he served as Professor of Preventive Medicine and Hygiene at Cornell University, Ithaca, N. Y., and during that time, directed the Cleveland Health and Hospital Survey. In 1921-1922, he was the Medical Adviser of the Veterans' Bureau. Since 1922, Dr. Emerson has been Professor of Public Health Practice and Executive Officer of the DeLamar Institute of Public Health at the College of Physicians and Surgeons of Columbia University. He has carried out directly, or in collaboration with others, a number of health and hospital surveys of American cities, and the survey of the health and medical facilities of the city of Athens, Greece, for the Health Section of the League of Nations.

Dr. Emerson received the Médaille d'Epidémie en vermeille, was decorated as Chevalier of the Legion of Honor by

the Republic of France, and received the Distinguished Service Medal from

*Haven Emerson, M.D.  
President-Elect, A.P.H.A.*

the United States Government. He is a member of the National Advisory Health Council of the National Institute of Health.

## NEW MEMBERS

*The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.*

### *Health Officers Section*

George W. Bushong, M.D., Tompkinsville, Ky., Director, Monroe County Health Department  
John F. Cadden, M.D., Calhoun, Ky., Health Officer, McLean County  
Dr. F. W. Caudill, Georgetown, Ky., Director, Scott County Health Department  
Taylor Center, M.D., Campton, Ky., Health Officer  
Lewis C. Coleman, M.D., 2904 Reisterstown Rd., Baltimore, Md., Madison County Health Officer  
Leonard A. Crosby, M.D., Williamsburg, Ky., Director, Whitley County Health Department  
Joseph W. Davis, M.D., 204 S. Wells St.,

Sistersville, W. Va., Director, Mobile Unit No. 2  
Rosier D. Dedwylder, M.D., Cleveland, Miss., Director, Bolivar County Health Department  
John W. Dukes, Hindman, Ky., Director, Department of Health  
E. E. Edwards, M.D., 422 S. Main St., Taylor, Pa., Health Officer  
G. W. Fishbaugh, M.D., Court House 303, Portsmouth, O., Health Commissioner  
Lynn M. Garner, M.D., Tuscumbia, Mo., Director, Miller County Health Department  
Marshall C. Guthrie, M.D., 15 E. Taylor St., Chevy Chase, Md., Medical Director, U. S. Public Health Service  
Thomas J. LaMotte, M.D., Box 314, Elkton, Ky., County Health Officer, Todd County

Hugh L. McCalip, M.D., Yazoo City, Miss.,  
Director, Yazoo County Health Department  
Thomas J. Pool, M.D., Ola, Ark., Field Agent,  
U. S. Public Health Service, Medical Director,  
Yell County Health Unit

Thomas N. V. Potts, M.D., D.P.H., Public  
Health Dept., County Hall, Wakefield,  
England, County Medical Officer and School  
Medical Officer (Assoc.)

Walter F. Stillger, M.D., Professional Bldg.,  
Hicksville, N. Y., Health Officer, Oyster  
Bay

Albert B. Tonkin, M.D., Riverton, Wyo.,  
President, State Board of Health

Milton W. Williamson, M.D., Greensburg, Ky.,  
Director, Green County Health Department

#### *Laboratory Section*

Winifred M. Ashby, Ph.D., 419 4th St. N.W.,  
Washington, D. C., Bacteriologist, St.  
Elizabeths Hospital

Lucius F. Badger, M.D., National Institute of  
Health, Washington, D. C., Commissioned  
Officer, U. S. Public Health Service

Henry A. Cotton, M.D., N. J. State Hospital,  
Trenton, N. J., Director of Laboratory  
Research in Mental Disorders

Walter LeRoy Mallmann, Ph.D., Department  
of Bacteriology, Michigan State College,  
East Lansing, Mich., Sanitary Bacteriologist

Herbert E. McDaniels, B.S., 6536 Emerald  
Ave., Chicago, Ill., Bacteriologist, State  
Department of Public Health

Mrs. Betty Morris, Hinton, W. Va., Clinical  
Laboratory Worker (private hospital)

John E. Noble, Rm. 200, District Bldg., Washington,  
D. C., Bacteriologist

Isadore Pilot, M.D., 185 N. Wabash Ave.,  
Chicago, Ill., Associate Professor of  
Pathology and Bacteriology, University of  
Illinois, College of Medicine

Anni Seppanen, M.D., Helsinki Eerikinkatu I,  
Finland, School Physician (Assoc.)

George W. Wheeler, M.D., 525 E. 68th St.,  
New York, N. Y., Assistant Professor of  
Applied Bacteriology, Cornell University  
Medical College

#### *Vital Statistics Section*

John H. Milligan, P. O. Box 87, West Falls  
Church, Va., Chief, Bureau of Vital Statistics,  
Health Department, Washington, D. C.

Hugo Muench, Jr., M.D., Dr.P.H., Rockefeller  
Foundation, New York, N. Y., Field  
Staff

Jessamine S. Whitney, A.B., 164-16 Cryder's  
Lane, Beechhurst, L. I., N. Y., Statistician,  
National Tuberculosis Association

#### *Public Health Engineering Section*

Harry S. Abell, C.E., P. O. Box 35, McLean,  
Va., Chief Sanitary Section, U. S. Veterans  
Admr., Washington, D. C.

Arthur W. P. Blohm, 2206 Walbrook Ave.,  
Baltimore, Md., Assistant Sanitary Engineer,  
State Department of Health

Paul F. Bovard, B.S., 964 Spruce St., Berkeley,  
Calif., Consulting Sanitary Engineer

Lewis V. Carpenter, Box 562, Morgantown,  
W. Va., Professor, Civil and Sanitary  
Engineering

Ross E. Garrett, B.S., 501 Carlson Bldg.,  
Pocatello, Idaho, City Public Health  
Engineer

William D. Hobro, 678 Fifth Ave., San  
Francisco, Calif., Chief Inspector of  
Plumbing

Edward O. Madison, Lebanon, Tenn., County  
Sanitary Officer

Charles E. Trowbridge, 50 Broad St., New  
York, N. Y., Sanitary Engineer, American  
Water Works and Electric Company

Arthur D. Weston, 15 Blackstone Terrace,  
Newton, Mass., Chief Engineer and Director  
Division of Sanitary Engineering, State  
Dept. of Public Health

#### *Industrial Hygiene Section*

Waldemar C. Dreessen, M.D., U. S. Public  
Health Service, Washington, D. C., Asst.  
Surgeon

James E. Ives, Ph.D., U. S. Public Health  
Service, Washington, D. C., Senior Physicist

Edward S. McSweeney, M.D., D.P.H., N. Y.  
Telephone Co., 140 West St., New York,  
N. Y., Medical Director

Louis Schwartz, M.D., U. S. Public Health  
Service, New York, N. Y., Studies of Industrial  
Dermatoses

#### *Food and Nutrition Section*

Reid R. Ashworth, D.V.S., 3533 Hertford Pl.  
N.W., Washington, D. C., Chief Food and  
Dairy Farm Inspector

Frederic H. Bartlett, M.D., 108 E. 79 St., New  
York, N. Y. (Assoc.)

Herbert B. Lerner, S.B., National Oil Products  
Co., Harrison, N. J. (Assoc.)

#### *Child Hygiene Section*

Dr. H. S. Berman, 10 Peterboro, Detroit,  
Mich., formerly with Infant Welfare Department,  
Detroit Department of Health

Henry A. Dirschedl, M.D., 613 W. Market  
St., Pottsville, Pa., Medical Inspector, Public  
Schools

L. M. Merrow, M.D., 720 Market St.,  
Mechanicsburg, Pa., formerly with State  
Health Department

Charlotte R. Rader, M.D., Laramie, Wyo.,  
Director of Health Work, Public Schools

Frances C. Rothert, M.D., U. S. Children's  
Bureau, Washington, D. C., Associate Medical Officer

Dr. Marion Stevenson, Houghton, Mich.,  
Ophthalmologist, Children's Fund of Michigan

Joseph S. Wall, M.D., 1864 Wyoming Ave.,  
Washington, D. C., former Director, Child Welfare Society

#### *Public Health Education Section*

Aurelia B. Cote, B.S., Seaford, Del., Director  
of Health Education, Public Schools

Nora S. Hamner, R.N., 1112 Capitol St.,  
Richmond, Va., Executive Secretary, Richmond Tuberculosis Association

H. Mac Hindman, R.N., Palo Alto Hospital,  
Palo Alto, Calif., Superintendent

Mrs. M. Pierson, B.S., 110 E. 14 St., Austin,  
Tex., Assistant Secretary and Treasurer, Texas Public Health Association

Charles M. Smith, M.D., Box 107, Dixon,  
Ky., Director, Webster County Health Department

Emma Stewart, B.A., 821 E. Washington St.,  
Ann Arbor, Mich. (Assoc.)

Philomena Supper, R.N., 100 Parsons St.,  
Detroit, Mich., Director, Department of Health Education, Marygrove College

#### *Public Health Nursing Section*

Marion H. Douglas, R.N., 55 Allyn St., Hartford, Conn., Executive Director, Visiting Nurse Association

Florence O. Eby, R.N., Betsy Barbour House,  
Ann Arbor, Mich., Student (Assoc.)

Mary B. Hulsizer, A.B., 31 Green St., Newark,  
N. J., Supervisor of School Nursing, Bd. of Education

M. Louise Nicol, 1228 Hamilton Blvd., Peoria,  
Ill., District Supervising Nurse, State Department of Health

Bertha McKay Ohr, 1707 Columbia Rd. N.W.,  
Washington, D. C., School Nurse

Katharine E. Peirce, R.N., 2203 Orleans St.,  
Baltimore, Md., Supervisor, Eastern Health District

Amanda M. Sheeler, R.N., 220 W. Main St.,  
Moorestown, N. J., Supervisor, Visiting Nurse Association

Elizabeth S. Soule, R.N., University of Washington, Seattle, Wash., Director, Department of Nursing Education

Willena Tracy, R.N., 104 Central Ave., Gladstone, Mich., City Nurse

#### *Epidemiology Section*

Charles Armstrong, M.D., 1001 Ohio St. N.E.,  
Washington, D. C., Surgeon, U. S. Public Health Service

Fred C. Bishopp, Ph.D., U. S. Bureau of Entomology, Washington, D. C., Medical and Veterinary Entomology

J. Davis Bradfield, 1010 Rhode Island Ave. N.E., Washington, D. C., Medical Inspector, Health Department

Stewart M. Grayson, M.D., 1833 New Hampshire Ave. N.W., Washington, D.C., Medical Inspector, Health Department

Claude H. W. Mitchell, D.P.H., Silver Spring National Bank Bldg., Silver Spring, Md. (Assoc.)

#### *Unaffiliated*

Joseph H. Kler, M.D., Rutgers University,  
New Brunswick, N. J., University Physician

Herbert C. Ober, M.D., DMD., 38 Eldridge St., Newton, Mass., Industrial Medicine, Hood Rubber Co. Inc.

#### APPLICANT FOR FELLOWSHIP

#### HEALTH OFFICERS' SECTION—

R. H. Markwith, M.D., Commissioner of Health, Summit County, Akron, O.

## TRAINING AND PERSONNEL

### REGISTRATION OF HEALTH OFFICERS AND ASSISTANT HEALTH OFFICERS

**I**N January, the Association will publish a Directory of Health Officers and Assistant Health Officers. This will be used in connection with the national movement to provide tenure of office for existing health officers and the appointment of experienced or trained health officers when new appointments are to be made.

If you are a health officer or assistant health officer, and have held such a position for 2 years or more and have not been out of the public health field for more than 2 years, your name should be on this list. Fill out and send to the Association the blank sent to you last spring, or if you have not received such a blank, write for one.

## LETTER FROM GREAT BRITAIN

A MEMORIAL TO THE LATE  
SIR ANDREW BALFOUR

THE ceremony of unveiling the memorial to the late Sir Andrew Balfour on October 6 was one of the most brilliant and largely attended that the London School of Hygiene and Tropical Medicine has seen. This was not surprising, for in the medical profession there are few who have had so many and such varied interests as Balfour, and none who has attained so high a place and earned so much of esteem and regard in each of his interests. From the fields of nearly all of his activities there were representatives met together to hear and express agreement with the glowing tribute paid to the memory of Sir Andrew by the Earl of Athlone, Chancellor of the University of London.

As explained by Sir Holburt Waring, of the Court of Governors, the suggestion that there should be a memorial to Andrew Balfour was very warmly welcomed by a very wide circle of his friends, and within the space of a comparatively few months a sum of over £2,000 (\$8,000-9,000) had been subscribed or promised. The greater part of this sum is to be devoted to the purpose of enabling students, preferably from overseas, to pursue courses of study in the School. The remainder was used to provide and erect a tablet to the memory of Sir Andrew Balfour in the entrance hall of the School. No one connected with that institution, for which London University is indebted to the Trustees of the Rockefeller Fund, is more deserving of such recognition as a tablet can offer than Andrew Balfour. It was the last piece of work to which he put his mind and that, as the Chancellor said, he "brought to fru-

ition, through 7 years of unremitting zeal, untiring energy, and an enthusiasm—nay, a passion—for the successful accomplishment of his task."

The very many friends he had in preventive medical and teaching circles in the United States of America will agree that there could be no description of Andrew Balfour from which the words zeal, energy, and enthusiasm could rightly be omitted. He was a tremendous worker, no matter where he was or what he did. Everywhere, and there was apparently no part of the globe where he did not work, and whatever the kind of it, all of it was inspired by zeal, energy and enthusiasm.

All of the greatness he attained—and I have thought often, knowing him intimately, that no one except Balfour himself, the most modest of men, was surprised at that greatness—came to him because of these three things. Also, and without doubt, they brought his life to his pathetic and untimely end at the early age of 58, for if it could be said of anyone at any time that he worked himself to death it could be said of Balfour. In the interests of the London School of Hygiene and Tropical Medicine and of the British Empire, if not, indeed, of the nations of the world, he worked and worried himself to death. With his passing there went out, as the Earl of Athlone described him, a man without guile, honest to the core, and one who evoked in his colleagues a spirit of love and sacrifice.

It is good that there should be in the hall of the School a permanent record of his devotion to the cause of tropical hygiene and of his self-sacrificing labors on behalf of the school. More appropriate still is it that, having regard to what he was and did, and for the encouragement of others also, there should

be upon the tablet these noble words of Walt Whitman: "Through the battle, through defeat, moving yet, and never stopping. Pioneers! O Pioneers!"

PROFESSOR CARL PRASNITZ AND THE  
TEACHING OF PREVENTIVE MEDICINE

**O**CTOBER with us always is a month of addresses, but never have I known one more replete with oratory than this one has been. The medical schools, which open in October, began it, each, in London at any rate, calling up someone more or less distinguished to tell the students just how wonderful a career they have chosen and to give a talk upon some subject he is particularly interested in. As the occasion is usually also that of the annual prize giving, and the students who have gained awards at any rate are bound to attend, the meeting is in general very pleasant and nice and in the main decorous.

Close on the heels of these school orations there have followed this October a multitude of others many of them upon preventive medical subjects and therefore of particular interest to members of the health service. Of outstanding importance have been the Heath-Clark Lectures of Professor Carl Prausnitz of Jena, and the Harveian Oration to the Royal College of Physicians of Sir George Newman, Chief Medical Officer of the Ministry of Health. As the first Heath-Clark lecturer—the course was only inaugurated last year—Sir George Newman took the chair at the first of Professor Prausnitz's lectures and presented him to the audience in the lecture theatre at the London School of Hygiene and Tropical Medicine. Not, as Sir George explained, that much in the way of introduction was necessary since, apart from the fact that he is known by his work, Carl Prausnitz attended school in England, studied for an English medical qualification in London, and held cer-

tain teaching and laboratory appointments before taking up work in Jena. As a result there was no language difficulty and when he addressed us it was as if we listened to one of our own university professors delivering a lecture. In his course Professor Prausnitz discussed "The Teaching of Preventive Medicine in Europe," and gave us the results not only of a very full investigation he had carried out in various schools in various countries but also of very serious consideration given to the whole subject. From the view submitted it was clear that considerable differences and divergencies exist, and that in every country some sort of attempt is being made to get the teaching placed on a sound and broad basis.

In this country, largely on the initiative of Sir George Newman, who some years ago issued a special report on the need for teaching preventive medicine in the medical schools and the methods that might be adopted, and more recently as a result of pressure brought to bear by the Society of Medical Officers of Health, the attention of the General Medical Council, the medical schools and examining bodies has been directed to the matter. The results that have followed the directing of this attention unfortunately leave much to be desired. The hope is nourished, however, that this visit of Professor Carl Prausnitz and the lectures he has delivered may have the effect of impressing upon the bodies mentioned, and more especially the teaching staffs of the medical schools in London and elsewhere, the need for recognizing more fully the great importance that should be given to preventive medicine in the medical curriculum.

THE HARVEIAN ORATION OF  
SIR GEORGE NEWMAN

**T**HOUGH the Harveian Oration has been delivered more or less continuously year by year on St. Luke's

Day since the inauguration of the feast by Sir William Harvey in 1656 in commemoration of benefactors of the Royal College of Physicians, of which he was a Fellow, not many of the orators have been engaged in the public health and preventive medical service. Even so it is doubtful if any had such claims to speak of preventive medicine or to be regarded as an orator as Sir George Newman. In choosing to speak of the advances made within the past century in the prevention and control of disease, Sir George provided himself with an opportunity of paying tribute to many benefactors not only of the College of Physicians but of mankind as a whole. Also he provided a treat for those privileged to be present in the beautiful library of the College, for when it comes to medical history Sir George is particularly apt to prove interesting to the point of fascination. On this occasion he certainly gripped his hearers, and had the surroundings been other than they were there might have been marked expressions of enthusiasm. However, it is difficult to be other than supremely conscious of a need for decorum when you find yourself surrounded by ceremony that

smacks of the 17th century, and by a collection of distinguished physicians all in scarlet robes, with Lord Dawson of Penn clad in a robe of black and gold in his place as President and with the golden mace resting upon its cushion before him.

By ancient custom the whole business of this meeting should be the oration, and at its end the President should depart in procession accompanied by the high officers and councillors. On this occasion there was a departure from the established order to permit of reference to the loss sustained by the death of Dr. T. H. C. Stevenson, Superintendent of Statistics in the office of the Registrar-General, to whom there had been awarded, but not presented on account of the illness that had proved fatal, one of the medals (the Bisset Hawkins Gold Medal) in the gift of the college. St. Luke's Day is a very full one for the Royal College of Physicians for, in addition to listening to the oration in the afternoon, they attended church in the forenoon to hear the Dame Sadleir Sermon and in the evening took part in a banquet. And so to bed. CHARLES PORTER, M.D.

# PUBLIC HEALTH ADMINISTRATION

## SHORT SCHOOLS FOR MILK CONTROL OFFICIALS

SARAH VANCE DUGAN

*Director, Bureau of Foods, Drugs and Hotels, Kentucky Board of Health  
Louisville, Ky.*

IN order to develop uniform procedures and improve methods of milk supervision in the State of Kentucky, the State Board of Health conducted in different sections of the state during August, 1932, three schools of instruction, each of 3 days' duration. One school, at Henderson, included the full-time health officers and inspectors of 11 counties; the sessions at Murray included the personnel of 7 counties; while those at Georgetown included the personnel of 12 counties.

Each school was located where space was available for the travel laboratory equipment loaned by the American Child Health Association and for a classroom for lectures and demonstrations. Lectures were given by representatives of the U. S. Public Health Service, the American Child Health

Association, and the State Board of Health. After the lectures dealing with special aspects of milk control, the class was divided each day into groups for dairy farm or milk plant inspections, for collection of route samples, or for laboratory demonstrations. The course covered safe water supply and waste disposal methods, including construction of practical toilets in rural areas.

Certificates were awarded to those who attended all the sessions of the course. Opportunity was given for free discussion and questions by students. As a means of informing a large number of inspectors and health officers of the methods of inspection, we believe that these schools were extremely valuable and that they stimulated greater activity in milk work in the county health units.

**New Health Center in Milwaukee**—On October 14, the new Matthew Keenan Health Center, made possible by a gift of \$175,000 from the trustees of the Keenan Endowment Fund, was dedicated. A modern L-shaped building two and one-half stories high has been constructed to serve as a health department headquarters and clinic center for the northwestern section of Milwaukee. This institution is dedicated not to the treatment of disease but to the conservation of health and the prevention of disease.

The services which the Health Center will provide will include consultation

and diagnostic service in chest conditions; X-ray facilities; public health nursing service; diphtheria, smallpox, and typhoid fever immunization; dental service for indigent children; eye, ear, nose, and throat consultation for indigent children; sanitary inspection; educational activities; and the promotion of child welfare. In addition to modern examining and diagnostic facilities, a small laboratory, dental clinics, an X-ray department, a large assembly room to serve the 27 public health nurses who work in this area is found on the second floor.

Popular health education has not

been overlooked as there is an auditorium with a seating capacity of more than 200 located in the basement. This auditorium contains a 20-foot wide stage with flood lights, curtain, and dressing room with a projection booth for motion pictures. This new health center is completely described and well illustrated in the October, 1932, *Bulletin of the Milwaukee Health Department*.

**Childhood Tuberculosis**—In June, 1921, the Lymanhurst School for Tuberculous Children was opened in Minneapolis. A 10-year progress report has been prepared. It is recommended that the present institution be enlarged in order to care for all children of school age who have demonstrable tuberculosis. The Mantoux intracutaneous test has been accepted as a standard because of its accuracy through its measured dosage of tuberculin and because it is desirable that such a test become the standard throughout the country. This test is used to screen out children suspected of having tuberculosis, the positive reactors being given the X-ray examination and more detailed physical examination. The need of careful history taking in every case is emphasized. The sharp line which was previously set up to separate tuberculous infection from tuberculous disease has been disregarded. Every child with a positive tuberculin reaction is looked upon as one with the first infection or the childhood type of tuberculosis. The report presents quite in detail many of the high points of the research work carried on at the Lymanhurst School.—J. A. Myers, *Childhood Type Tuberculosis*, Lymanhurst School for Tuberculous Children, Minneapolis, 1932.

#### HEALTH DEPARTMENT REPORTS

**Madera County, Calif.**—The first comprehensive report rendered by the health unit in this county of 17,164

covers the period April 1, 1931, to May 31, 1932. This is a very readable document, containing sound philosophy as well as local factual material. In addition to the services of the county health officer, county nurse, and school nurse, the county received coöperation from the state department of health in the conduct of baby clinics, 2 or 3 days a month, the estimated cost per day being \$10. Several calculations are made to show the financial value of the unit to the county. For example, a smallpox vaccination campaign conducted during the year would have cost the county, had the work not been done by a health officer, close to the total amount spent for the health unit in a year. Following a case of psittacosis contracted from a love bird with the disease, a regulation was prepared by the county to govern the sale of love birds and parrots.

**East Orange, N. J.**—The 1931 health report is well up to previous high standards obtained by the earlier records. In connection with preschool work, the department has gone a step in advance of the delivery of birth records to mothers by nurses. With postcard acknowledgments to physicians, the doctors are asked whether at the end of 6 months they will vaccinate and immunize the new child, or prefer that these procedures be carried out by the health department. Of the doctors returning these cards, 20 per cent referred the procedures to the department. A letter urging the necessity of these protective measures is addressed to each parent when the child is 6 months of age, and with the letter is a postcard to be returned to the department with the necessary data for record when the procedures are completed. When the child reaches 1 year of age, a birthday letter is sent to him personally. This greeting urges not only protection against smallpox and diphtheria, but promises a Blue Ribbon

Certificate of Merit with the department's seal to all children who have not only had these protections but have had a complete medical and dental examination with correction of such defects as are discovered during the year before entrance to school.

**Montclair, N. J.**—Included in the comprehensive report of health activities for 1931 is a record of the first year of the generalized program in the amalgamation of the nursing service of the community under a bureau. A marked increase in the volume of nursing service rendered seems to be the experience since generalization was introduced. A saving in the budgets of various nursing agencies is noted in spite of reduced collections. Office management, supervision, and record work were simplified.

**Hygienic Institute, Ill.**—This 17th annual report, for the year 1931, contains an attractive photograph of the health center, a detailed organization chart, and a reproduction of the U. S. Chamber of Commerce award to LaSalle for accomplishments in health conservation. Immunization work has been extended in the health unit area, and communicable disease incidence was low. There has been but 1 death in 8 years from diphtheria in the population of 26,180.

Attention is directed to school physical examination records for the latter part of 1931 which indicate increased underweight, increased carious teeth, and lower percentage of correction of defects.

**Kanawha County, W. Va.**—In the space of a few well printed pages, bound in attractive covers, the county health officer has prepared a report of the health unit which is clear, interesting, and convincing. In the education field, school teachers provide health certifi-

cates, most of the examinations being made by the health officer. Some two-fifths of the population have been immunized against typhoid, while 50 per cent of the children under the teen age have been given protective doses against diphtheria.

Prior to the institution of the health unit, it was not unusual to have 300 to 500 cases of smallpox in the county every winter. Not over 10 per cent even of the teachers were protected. The 30,000 school children are reported protected, as well as the teachers. The people of the country "are free from this disease and there is no danger of its return while they practice prevention."

**Los Angeles County**—The California Taxpayers' Association in July, 1932, published a report of a survey of public health services in Los Angeles County which is of more than passing interest to administrators. There are 4 major health departments in the county, those of Los Angeles County, Los Angeles City, Pasadena, and Long Beach, beside a few small local departments. The county health department handles all health problems in the rural areas and in 35 of the 45 incorporated cities. The 3 city health departments handle the health problems within their respective areas and also inspect dairy farms in several other counties.

The survey report shows existence of duplication *between* and *within* departments. "Overlapping of responsibility and duplication of services now performed by the larger public health agencies in Los Angeles County can be eliminated by combining them into one department. A merger of the health services of Los Angeles City, Pasadena, and Long Beach under contract with the county would result in estimated savings of at least \$200,000 annually." The report shows that taxpayers within these larger cities having their own

health departments are also aiding in the support of the County Health Department—an investment from which they receive no return.

Winnipeg, Canada—In 1931, a resident death rate of 7 per 1,000 people, and an infant mortality rate of 49 (per 1,000 live births) are recorded. These are commendable records for this city of 212,815. The net costs per capita of services for which this health department is made responsible are interesting: control and prevention of disease (strictly health service) \$.59; scavenging and refuse disposal \$1.09; street cleaning and flushing \$.47; public comfort stations \$.14; public baths \$.22.

With reference to infant hygiene work, the report indicates that the visiting nurses are regarded as the first line of defense against disease, there being 39,797 calls made to babies' homes by 13 nurses, in addition to 180 visits to boarding homes. The 6 child welfare stations form the second line of defense, proving useful for keeping in contact with infants not requiring regular home visiting, and for preschool children who have been dropped from the nurses' visiting lists. There was an attendance of 9,125 for 289 afternoon sessions. The Babies' Clinic for feeding cases at the Milk Depot forms the third line of defense. To the clinic are referred cases which require modified feedings when parents cannot afford a private physician.

Territory of Hawaii—A very careful and thoughtful analysis of the tuberculosis problem in the Territory of Hawaii has been made by the Tuberculosis Committee of Palama Settlement, organized in 1931. The 84-page report is well illustrated with charts,

graphs and statistical tables. The task of bringing together and digesting a large amount of data was a joint community enterprise, and the foreword gives particular credit to a committee of the American Association of University Women.

The Territory of Hawaii consists of 8 inhabited islands divided into 5 counties with a total population of 375,000. The governmental expense is about 12 million dollars annually, with 1 million roughly for the Board of Health. Nineteen per cent of the health budget was for tuberculosis hospitals. The total estimated expenditure for all phases of tuberculosis work in 1931 was approximately \$1.80 per capita. Tuberculosis, the third cause of death, causes approximately 400 deaths annually in the Territory. For the past 4 years, 2.72 cases per annual death have been reported.

The Board of Health was established in the islands in 1850; tuberculosis was given attention in the program in 1900; and a separate tuberculosis bureau was created in 1910. There is in Honolulu a complete chest clinic under the Board of Health. Leahi Home (sanatorium) holds semi-monthly clinics for follow-up of discharged patients. A semi-monthly diagnostic clinic was also held during 1931 at the Japanese hospital. In addition, 35 chest clinics are held in various localities in rural districts of the Islands. There are preventoria on all the large islands, actively utilized. There are only 56 public health nurses in the Territory, most of them on a generalized basis, all effectively organized. The new Tuberculosis Committee has launched upon an active education program, and has already obtained commendable results from its first Seal Sale Campaign.

# LABORATORY

## THE APPLICATION OF A YEAST EXTRACT MEDIUM TO A TEST FOR DETERMINING QUALITY OF MILK \*

E. D. DEVEREUX

*Michigan Agricultural Experiment Station, East Lansing, Mich.*

IN an effort to find a method which would give a reading more nearly representing the actual ability of the bacteria and enzymes present to produce the changes in milk of interest to the producer and consumer, the bromthymol blue milk test or colorimetric hydrogen ion method for determining the keeping quality of milk was devised by Cooledge<sup>1, 2</sup> in 1920. Several optional changes were suggested by Devereux<sup>4</sup> in 1928. The correlation coefficient between the test and the keeping quality was found by Cooledge to be + 0.75. In a comparison of the bromthymol blue test and the methylene blue reduction test Devereux<sup>5</sup> found the coefficient for each test to be + 0.77, which confirmed the work of Ellenberger et al.<sup>3</sup> on the methylene blue test, their coefficient being + 0.72 ± 0.02.

From the above data it may be concluded that the two tests are comparable as judged from the standpoint of accuracy. The methylene blue test is more easily applied, requires less equipment, and readings are made after relatively short incubation periods (20 min., 2½ and 5½ hours). However, short incubation periods might at times be a disadvantage in that they require the attention of the operator for several hours after starting the test, a point which has been called to our at-

tention. The bromthymol blue test does not require the attention of the operator, in the great majority of cases, for 6 hours after the tubes have been inoculated.

### EXPERIMENTAL

In an effort either to shorten the incubation period or improve the efficiency of the test, or both, a yeast extract medium<sup>6</sup> was substituted for the Cooledge broth. This new medium differed from the Cooledge broth in that dextrose was added, and yeast extract and peptonized milk were substituted for beef extract and peptone. The complete formula is given here.

#### YEAST EXTRACT MEDIUM

Yeast extract (Difco)	5 gm.
Peptonized milk (Difco)	10 gm.
Sodium chloride	5 gm.
Dextrose	10 gm.
Dibromthymolsulphonaphthalein (Bromthymol blue)	0.020 gm.
Distilled water	1,000 c.c.
Adjusted to pH = 7. Autoclaved at 15 lb. for 15 minutes.	

In the experimental work with the yeast medium the test was compared to the actual keeping quality of the milk, using time as the standard.

One hundred 200 c.c. samples of milk were taken in 250 c.c. sterile Erlenmeyer flasks from the receiving vats of two dairies. The test is made by adding 0.1 c.c. of the milk in question to 10 c.c. of bromthymol blue broth

\* Journal Article No. 120 (n.s.), from the Michigan Agricultural Experiment Station.

and noting the rate of pH change when incubated at 37° C. until a pH of 5.8 is reached or until the tube has been incubated for 8 hours.

Bromthymol blue color standards\* having a pH range of 5.8 to 7.4 (5.8, 6.0, 6.2...., 7.4) are used for making the readings.

Broth without the indicator is also prepared and used in the compensating blanks. The compensating blanks are inoculated and incubated in the same manner as the broth tubes containing the indicator. It is necessary to prepare only two compensating blanks for one day's run on any one batch of samples.

When it is desired to make a reading, the tubes and the compensating blanks are removed from the incubator, cooled to 20° C., and placed in the comparator. The top view of the arrangement of the tubes in the comparator when a reading is to be made is given below.

Additional  
storage  
space  
for color  
standards

Additional  
storage  
space  
for color  
standards

- S = color standard  
W = water blank  
C B. = compensating blank  
U = unknown containing the milk in question

The unknown is compared to the color standards and the pH noted.

Cooledge devised a table in order that the milk could be scored, its keeping quality determined, and the purpose for which it is best suited determined. From experience with this table the author is of the opinion that milk

scoring 70 or better is suitable for milk plant supply.

The keeping quality was measured by the time required for the milk to become unfit for table use as determined by taste. The samples were held at 18° to 20° C.

TABLE  
THE COMPARISON OF THE BROMTHYMOL BLUE TEST AND THE KEEPING QUALITY OF MILK

Time of Souring Hours	Number of Samples	Bromthymol Blue Test Yeast Extract Medium	
		Score range *	
24	13	35-55	53.5
26	7	35-55	49.3
28	9	35-55	52.7
30	12	60-75	66.6
32	12	60-75	66.0
34	6	80-100	79.1
36	13	80-100	77.3
38	9	80-100	80.0
40	2	80-100	77.5
42	1	80-100	85.0
44	3	80-100	90.0
46	13	80-100	98.0

100

* Score range	pH	Score	Milk Suited for
Reading hours			
1, 2, 3	5.8	20-30	Condemning
4, 5, 6, 7, 8	5.8	35-55	For butter making
8	5.9-6.2	60-75	Condensing
8	6.3-6.7	80-100	Market milk or cheese making

In the table the results are arranged according to the time required for the samples to become unfit for use. Since souring was, in the great majority of the cases, the first undesirable quality displayed, the column is headed "Time of souring." The individual cases, that is, the score of each sample (data too voluminous to present), not the average scores, was used to calculate the correlation coefficient between the test and the keeping quality. The coefficient was found to be +0.86 ± 0.02, which indicates a decided increase in the efficiency of the test when the new medium was employed.

Duplicate tests were made on 50 of

\*The test has been so devised that the color standards and comparators, of either the Hynson, Westcott, Dunning & Co. (use test tubes with a diameter of 1.6 cm.) or the LaMotte Chemical Products Co., can be employed (use tubes with a diameter of 1.5 cm.).

the samples using broth made according to the old formula and it was noted that acid development was more rapid in the yeast medium. This was particularly true with milk having a score of 50 or below according to the yeast medium. There were not enough samples of poor quality milk examined to warrant any conclusions on this point. While it was apparent that poor milk could be detected 1 to 2 hours sooner when the new medium was employed, insufficient data prevented the determination of the accuracy of the medium on milk of poor quality.

#### SUMMARY AND CONCLUSIONS

By changing the formula of the medium used in the bromthymol blue milk test the correlation coefficient between the test and the actual keeping quality of the milk was increased from  $+0.75$  or  $+0.77$  to  $+0.86 \pm 0.02$ ; which is also an increase in accuracy over the methylene blue reduction test.

There were indications that the use

of the new medium would permit earlier detection of milk of poor quality. The employment of this test, regardless of medium used, does not require the attention of the operator, in the great majority of the cases, for 6 hours after the tubes have been inoculated. The test, due to its high degree of accuracy and applicability, should be applied to the determination of quality of other dairy products.

## A YEAST EXTRACT MEDIUM FOR THE EXAMINATION OF MILK \*

E. D. DEVEREUX

*Michigan Agricultural Experiment Station; Michigan State College,  
East Lansing, Mich.*

DURING some recent researches on the isolation of lactobacilli and streptococci from the oral cavity a yeast extract medium was devised. Later, the ability of this medium to support the growth of milk organisms was determined; in addition to the common milk organisms this experiment included: *Lactobacillus acidophilus*, *L. bulgaricus*, *Brucella abortus*, *Streptococcus mastitis*. In brief the results were that the yeast extract medium in

either the broth or the agar form produced luxuriant growth of the common milk organisms. *L. acidophilus* and *L. bulgaricus* grew excellently in the broth and colonies of sufficient size were obtained in the agar medium that they would not be missed in routine plate counting.

*B. abortus* could not be isolated directly from infective milk by this medium: however, it did support the growth of laboratory cultures of this organism. *S. mastitis* also failed to appear on plates made from infective

\* Journal Article No. 97 (n.s.), from the Michigan Agricultural Experiment Station.

milk, but excellent growth was obtained in the yeast extract broth and agar media when laboratory cultures were used.

Needless to say, the above mentioned organisms grow very slightly if at all in plain nutrient broth or agar.

#### YEAST EXTRACT BROTH

Yeast extract (Difco)	5 gm.
Peptonized milk (Difco)	10 gm.
Salt	5 gm.
Dextrose	10 gm.
Water	1,000 c.c.

Adjust pH to 7.0; autoclave for 15 minutes at 15 lb. pressure.

To prepare the agar 15 gm. of washed agar are added to each liter of the broth, which necessitates dissolving in a steamer or autoclave.

At the present time several applications are being made of this medium; one using the broth, containing an indicator, for determining keeping quality of milk and one using the agar for determining the bacterial content of milk.

## VITAL STATISTICS

**Provisional Summary of Mortality from Automobile Accidents, 1931—** The Department of Commerce has announced that during the calendar year 1931 in the death registration area of continental United States, exclusive of the State of Utah, there were 29,547 deaths from automobile accidents, not including collisions of automobiles with railroad trains and with street cars. In 1930, in the same area, there were 28,950 deaths from this cause. The death rates were 24.9 and 24.5 for the respective years. The estimated population of the United States death registration area, exclusive of Utah, was 118,051,800 in 1930 and 118,740,600 in 1931. In these two years 47 states, the District of Columbia, and the 8 registration cities in the nonregistration State of Texas composed the area in continental United States, or 95.7 per cent of the total population.

Considering the states by geographic divisions, the Pacific group had the highest death rate in 1931 as well as in 1930. The rate was 34.6 per 100,000 population in each year. Next in order of groups in 1931 are the Mountain (28.9), the East North Central (28.0), and the Middle Atlantic (25.3)—each

higher than the rate for the registration area in either year. Contrasting these high rates with the low rates of the West South Central group (17.5), the East South Central (18.2), and the New England groups (20.8), it would appear that in the more thickly populated centers fewer automobile accidents take place.

Considering the states separately, those with the highest death rates from automobile accidents in 1931 were Nevada (68.5), Wyoming, (43.0), California (36.8), Florida (34.4), and Arizona (34.3), while in 1930 the order was Arizona, California, Florida, Nevada, and Wyoming. The rate for Nevada almost doubled, or 68.5 in 1931, as compared with 37.4 in 1930. The lowest mortality rates from this cause in 1931 were for Mississippi (14.0), North Dakota (16.1), Arkansas (16.5), Oklahoma and South Dakota (each 16.6), and Rhode Island (16.7). States with the lowest rates in 1930 were, in order of rate, North Dakota (11.6), South Dakota (16.1), Arkansas and Mississippi (each 16.5), Alabama (17.3), and Louisiana (17.6).

In the group of 92 cities of 100,000 or more population there were 9,594

deaths, or a rate of 25.9 per 100,000 population from automobile accidents in 1931, as compared with 9,555 deaths or a rate of 26.3 in 1930. The cities which had the highest mortality rates from automobile accidents in 1931 were Camden (84.0), Miami (52.4), Richmond (48.8), Chattanooga (47.5), Nashville (45.7), Jacksonville and Gary (each 42.5), San Diego and Indianapolis (each 42.2), Trenton (42.0), Tampa (41.0), Columbus (40.9), Toledo (40.4), and Bridgeport (40.1). Considering only accidents within the city limits, for certain cities, Trenton's rate was only 9.7, Camden's 31.1, Richmond's 22.2, Chattanooga's 23.7, and Tampa's 21.0.

The total number of deaths within a city should not be taken as the measure of the automobile hazard. The location of the city with reference to automobile traffic, the volume of traffic, hospital facilities, and other factors, should be considered. Camden, N. J., serves as an excellent illustration of this statement. There occurred 100 deaths due to automobiles in that city in 1931, but only 37 were due to accidents within the city limits. The remainder (63) were due to accidents outside. Other cities—Fort Wayne, Nashville, Richmond, Tampa, and Trenton—show large reductions when measured by this standard.—*Provisional Summary of Mortality from Automobile Accidents*. Dept. of Commerce. Bureau of the Census. Division of Vital Statistics. 1931.

**Infant Mortality Among Negroes in New York City**—During the past 20 years the infant mortality rate in the city of New York has dropped almost 50 per cent, the rate averaging 107 per 1,000 live births in the 5 years 1910-1914, and 59 during the past 5 years. Among the negro population in this city the corresponding figures were 209 and

104. In other words, the measures taken to reduce infant mortality were fully as effective among the negroes as they were in the rest of the population. While this is very encouraging, the fact that the infant death rate among negroes is almost double that among the population of the city as a whole, indicates the need of concentrating control measures on the sections of the city having large negro populations. Analysis of infant deaths according to cause, shows that tuberculous disease causes an undue proportion of deaths of negro infants. Whereas the infant death rate from all causes in negroes is approximately double the rate for the city as a whole, in tuberculous disease it is about 4 times the city rate. In infant deaths charged to malformations, the rate is actually lower among negroes than it is in the entire population. It is difficult to say whether the figures for this cause of death are significant for the number of deaths charged to negroes against malformations is small. Moreover, the death rate for "diseases of early infancy" (*International List* 1929 revision, Nos. 158-161) is distinctly higher among negroes.

Closely associated with infant deaths, are puerperal deaths. Among the general population of New York City, the death rate from puerperal causes has remained around 5 per 1,000 live births (6 in 1931); among negroes during the same period, it has been about twice as high, ranging between a low rate of 8 per 1,000 live births in 1923 and 15 in 1920. The puerperal death rate among negroes in New York City in 1931 was 13.—New York City Dept. of Health. *Weekly Bull.*, 21: 233-234 (July 30), 1932.

**Pernicious Anemia in Toronto, Canada, 1923-1926 and 1928-1931**—A review of the mortality statistics for Toronto, Canada, discloses a remarkable change in the death rate from

pernicious anemia since Minot's and Murphy's important discovery in 1926, of the benefits of liver therapy for patients afflicted with the disease. Allowing for certain influencing factors, such as the tendency toward better diagnosis, and differences in methods of classifying the causes of death, the death records for pernicious anemia in Toronto and elsewhere are none the less indicative of the great value of this new therapeutic agent.

In Toronto in 1927, the year immediately following the introduction of liver therapy, the death rate from pernicious anemia was reduced by nearly one-half, and the new lower rate has more or less continued throughout the past 4 years.

For purposes of comparison between the two periods of time, before and after the use of this new treatment, and in order to illustrate more effectively the substantial reduction that has taken place in the pernicious anemia death rate, the years 1923-1926 inclusive, and 1928-1931 are combined to make two 4-year periods. The year 1927 is excluded because its inclusion would result in differences of rates which would be of a negligible quantity. There was a total of 300 deaths attributed to pernicious anemia in Toronto during the period 1923-1926, this number of deaths representing a rate of 13.7 deaths per 100,000 population, while in the period 1928-1931 the number of deaths from this cause was reduced to 184, or a rate of 7.5. This marks a reduction in the death rate of over 45 per cent following the introduction of this new therapeutics.

Analysis of the pernicious anemia deaths according to sex and age groups, reveals interesting changes similar to those that have taken place in the statistics for diabetes mellitus after medical research had produced the insulin treatment. A prolongation of life is significant in the mortality records for both of these diseases.

In the case of pernicious anemia, comparison between the two selected periods shows that following liver therapy, 6.3 per cent more males and 12.9 per cent more females at time of death had attained the mark of 55 years of life or more. Excluding the more extreme ages at either pole of the life span (in which the occurrence of pernicious anemia is more or less uncommon), it is found that between the ages of 25 and 84, the average age at death has increased thus far, 3.6 years for males, and 4.5 years for females.

Specific death rates by sex and age groups between 35 and 79 years show, throughout, higher rates for females; they also indicate substantial reductions when comparison is made of the rates between the two 4-year periods, 1923-1926 and 1928-1931. Between the ages of 35 and 49 years inclusive, a greater reduction is shown for females than for males. The percentage reduction in the female rate is 75 as compared with 64.5 for the male specific rate. Above the age of 49 years, there is a greater reduction in the male rates. For males 50 to 64 years of age, the percentage reduction is 58.9 as against 51.5 for females; for the age group 65-79 years (the age which produces the highest rate of mortality from pernicious anemia), the reduction in death rate for males is 36 per cent or more than double the percentage decrease for females.—*Monthly Report of the Department of Public Health of the City of Toronto, Ontario, Canada, July, 1932, p. 1-3.*

Vital Statistics for New Zealand, 1931—Following a slight increase in 1930, the number of live births registered in New Zealand during 1931 continued on the downward trend, a total of 26,622. The birth rate, which has shown an uninterrupted decline since 1920, reached the lowest level on record with a rate of 18.42 per 1,000 of mean population. This compares

with a rate of 18.80 for 1930, a decline of 2 per cent. Fifty years ago, in 1882, the birth rate was 37.32 per 1,000 of mean population. Expressed in a more effective way, if the rate prevailing in 1882 had been recorded in 1931 on the present population, there would have been approximately 53,923 children born in the Dominion during the latter year, instead of only 26,622.

In spite of an abnormal year embracing a disastrous earthquake and an increase in virulence of influenza, the record of deaths for 1931 is much more satisfactory than that for 1930. Altogether 12,047 deaths were registered, as against 12,199 in the previous year. The corresponding death rates are 8.34 per 1,000 of mean population in 1931, and 8.56 in 1930.

The most remarkable feature of the vital statistics for 1931 is undoubtedly the phenomenal drop in the already very low infant mortality rate. In 1930 this rate stood at 34.48 per 1,000 live births, a figure slightly in excess of that recorded for the previous year. The interrupted downward movement, however, was again resumed in 1931, when the rate fell to the unprecedentedly low level of 32.15 per 1,000 live births. This represents a decrease of 68 in the actual number of infants succumbing during the first year of life. The decrease in the number of infant deaths registered in 1931, as compared with 1930, has taken place principally in the group of "diseases peculiar to early infancy."

The stillbirth rate in New Zealand shows a rising tendency, but this is not sufficient to reverse the trend of the declining infant mortality rate when

stillbirths are taken into consideration with this latter figure. The unusually large decrease in both the number of infant deaths and of stillbirths for 1931 has had the effect of reducing the combined rate or "total infant mortality" to an unprecedentedly low level.

The health record of New Zealand for 1931 is even more satisfactory than that for the previous year. Improvements have been effected in unexpected directions, while very few outstanding increases in important causes have been recorded. With the exception of influenza, epidemic diseases were particularly quiescent during 1931. No deaths from measles were reported and a new low level for diphtheria (0.38) was reached. A most important feature is the reduction of 32 in the number of deaths from all forms of tuberculosis, bringing the death rate down to 35.5 in 1931, as compared with 45.5 in 1930. Principal diseases of the respiratory system, other than tuberculosis, also show a decrease of 196 deaths, or a 21 per cent reduction. Other important decreases were recorded for heart disease, which declined from a death rate of 203.3 in 1930 to 195.0 in 1931, meningitis from 4.9 to 2.8, and cerebral hemorrhage from 46.2 to 43.9, for the years 1930 and 1931 respectively.

On the other side of the picture, the cancer death rate increased from 101.9 in 1930 to 103.3 in 1931, influenza from 9.2 to 15.3, suicide from 13.5 to 15.6 and the death rate from accidental causes from 54.2 to 64.1. This marked increase in accidental deaths was due primarily to the earthquake on February 3, 1931.—*Report on the Vital Statistics*. New Zealand, 1931, pp. 5-12

# PUBLIC HEALTH ENGINEERING

1. View of track drainage filter bed on reservoir side of railroad

## FILTRATION OF RAILROAD TRACK DRAINAGE ALONG A MUNICIPAL WATER SUPPLY RESERVOIR

E. B. MYOTT

*Fay, Spofford and Thorndike, Consulting Engineers, Boston, Mass.*

THE City of Gloucester, Mass., recently built an auxiliary water supply reservoir which will furnish about 1 million gallons per day during extremely dry periods.\* The watershed of the reservoir lies adjacent to the built up portion of the city, but with the exception of 7 houses remotely situated from the reservoir, it is free from habitation and consists largely of undeveloped land. It is traversed, however, by a state highway and a railroad. The highway did not present any particular problem from a sanitary

viewpoint as all land adjacent to the highway could be acquired by the city, and, moreover, the highway was not in close proximity to the reservoir. The railroad, however, did present a problem which was given careful consideration since it caused much concern to the Massachusetts Department of Public Health, which has jurisdiction over all water supplies in the Commonwealth.

There are between 30 and 35 passenger trains operated over the railroad each day. The reservoir, which is nearly a mile long, lies adjacent to the railroad the greater part of its length, the normal water level being about 7

\* See "Babson Reservoir—Built in Six Months" in *Am. City*, Sept., 1932.

2. View of track drainage, filter bed on far side of railroad from reservoir. Effluent from filter bed passes under railroad through old railroad culvert

feet below the lowest part of the track. The gate house at the dam, where the water enters the distribution system, is only about 1,000 feet from the nearest point where the reservoir adjoins the railroad. The reservoir is small, having a capacity of 200 million gallons, of which 178 million gallons are usable. This is equivalent to about 178 days' supply on the basis of the safe yield of the reservoir. It is quite probable, however, that the stored water will be used at times in a much shorter period.

The engineers on this project were of the opinion that the possibility of the track drainage polluting the water supply was remote because toilets in the trains could be locked and their use prohibited while the trains passed through the watershed, the soil along the railroad was gravelly, and the track was ballasted with cinders. It was felt, also, that some natural purification would prevail in the reservoir; moreover, chlorination of the water would have provided sufficient protection against pollution if it were deemed necessary.

The Massachusetts Department of Public Health recommended that con-

sideration be given to the removal of the track drainage from the watershed. Studies showed that the practicability of such a scheme was questionable as it would have been necessary to build a watertight drain underneath the reservoir, extending to a point of discharge below the dam; the cost of the work would have been prohibitive. Subsequently, studies were made in conjunction with the engineering division of the Department of Public Health which indicated that a feasible method of safeguarding the purity of the supply would be by filtration of the track drainage, the effluent to be discharged into the reservoir. This method was approved by the department and the necessary works were built. This precaution was in conformity with one of the long established policies of the department, which requires that any possible pollution of public water supplies must be dealt with at its source before the water reaches the reservoir. The scheme of filtering the track drainage for precautionary protection against pollution is entirely practicable and no doubt worth while, particularly in the case of a small reservoir.

The work involved the construction of paved gutters and ditches along both sides of the track, where necessary, to collect the drainage and carry it to sand filter beds which were built at convenient low points along the railroad right of way. The sites of the beds were cleared, grubbed, and roughly leveled. The filter beds consist of 3 to 4 feet depth of sand of the same characteristics as that used for fine aggregate in concrete. No underdrains were provided in the beds. The capacity of the beds was designed for a rate of run-off, as computed by the rational method, using a rainfall intensity curve of 10-year frequency. The areas of the beds were computed for a filtration rate of 10 million gallons per acre per day. This basis of design is conservative; smaller beds might possibly have served the purpose fully as well as those built.

Six filter beds, having a combined total area of about 6,800 square feet, about 4,000 linear feet of paved gutters, and about 450 linear feet of ditches

were built to handle the drainage from about 4,000 linear feet of track. The construction cost, exclusive of engineering, was \$5,900 for the filter beds and \$6,300 for the paved gutters and ditches. The total construction cost per foot of track drained was \$3.05.

All construction work was done by the railroad through agreement with the City of Gloucester, which agreement further provides that all maintenance and repair work be done by the railroad at the city's expense. The railroad insisted upon these requirements so that it would not be necessary for any city employees to work on their right-of-way. An enabling act was passed by the Massachusetts Legislature authorizing the city officials to enter into this agreement with the railroad.

The railroad has coöperated fully with the city in the protection of the water supply. A standing order is in force requiring toilet doors in all cars to be kept closed and locked between stations where the reservoir is located.

## INDUSTRIAL HYGIENE

**Doing Away With the Open Window in the Hospital**—Air conditioning and sound control will be the most important subjects in hospital construction of the near future. The necessity of controlling outside noises necessitates changing the present form of window construction. Windows must be kept closed.

By the use of double or triple glass, with an air-space between, noise and draft, odors, dust, pollen, insects, etc., can be kept out, light at the same time being admitted. Such will also reduce by 50 per cent the expense of cleaning rooms, curtains, and draperies and the wear and tear on furniture and fabrics. The death rate alone from window accidents is enough to condemn windows and eliminate them from new construction.

Proper window construction will also keep out cold in winter and heat in summer. "By using a single glass, on a zero day with an inside temperature of 70° F., the glass surface temperature will be 17.3° F. With double glass the surface temperature will be 49° F., and with triple glass the surface temperature will be 59.9° F.

By means of a type of unit or cabinet ventilator for each room, air can be taken from the outside, filtered, humidified when necessary, and heated to the proper temperature in winter and cool in summer. The device can be made automatic, thus maintaining the desired temperature without requiring any continual regulating by hand. Even the steam radiator is removed. Such cabinets can be plugged in like a radio and will do away with large expensive power plants.

At the same time roofs and ceilings

will be insulated and reduce the first cost of heating plant by 60 per cent.

"By actual tests, for two winters, in several insulated buildings in Ontario, the temperature has not gone down below 30° F., although the outside temperature had dropped to 17° below zero. Yet no heating plants are installed in these buildings. The only heat available to keep them above the mean temperature outdoors during periods of extreme cold weather, is supplied by the sun and earth." (James Govan, architect, Toronto, *Transactions of A.H.A.*, 1931, p. 346.)

Even electric fans will be eliminated and cool, fresh, clean air will be gently diffused in every part of the room.

This temperature control will have a marked effect not only on patients but on the health and efficiency of employees as well. It would be a boon to asthma and hay fever patients.—Asa S. Bacon, Superintendent, Presbyterian Hospital, Chicago, *Modern Hosp.*, 39, 2:37-38 (Aug.), 1932. E. R. H.

**The Influence of the Humidity of the Air on Capacity for Work at High Temperatures**—Author's summary:

The physiological action of two subjects was investigated in air at a temperature of 70-100° F. and of 40-92 per cent of relative humidity. The experiments lasted 3 hours, and one of the subjects performed mechanical work (step climbing) at the rate of 14,000 kg. m. per hour.

The pulse rate was about 10 beats greater in dry air than in moist air of the same wet-bulb temperature. The winter observations agreed well with the effective temperature scale, but did not agree with the wet bulb, the dry bulb or the kata-thermometer scales.

Acclimatization effects showed themselves in experiments made at a dry-bulb temperature of 87° F. or more, but only very slightly in those made at 81° or less. Acclimatization was fairly well marked in the summer, the pulse rate being 5 to 10 beats less than in the winter, and no longer agreeing with the effective temperature scale.

The body temperature corresponded with the pulse rate, for it was 0.3–0.6° F. higher in dry air than in moist air of the same wet-bulb temperature, and was 0.15° lower in summer than in winter. The winter observations agreed well with the effective temperature scale.

The skin temperature of the face was found to depend on the dry-bulb temperature of the air, but that of the trunk showed no agreement with any of the scales. In moist air it was 1° F. lower than that of the face, and in dry air, 6° lower, owing to the cooling effect of increased sweating.

The gross mechanical efficiency fell off slightly at temperatures above 70 or 75° F. It was affected by the dry-bulb temperature of the air as well as the wet bulb, but not to the extent indicated by the effective temperature scale.

The weight of moisture lost by sweating corresponded well with the effective temperature scale. It increased gradually in consecutive experiments made in dry air, and diminished in those made in moist air.

The degree of fatigue experienced in dry air was considerably greater than in moist air of the same wet-bulb temperature, and it corresponded with the effective temperature scale.—

H. M. Vernon and C. G. Warner, *J. Hyg.*, 32, 3:431–463 (July), 1932.

**Projected Study on Workmen's Compensation**—The Bureau of Medical Economics outlines some of the more important phases and tentative conclusions of its study of workmen's compensation.

The American compensation system (for industrial accidents and occupational diseases) came early to emphasize legal and financial features to the almost total neglect of the medical side. Physicians in the United States showed little interest in a movement that, within a generation, was to be a dominating influence in the practice of a considerable percentage of them.

At first the function of the physician was primarily that of an expert witness and in some instances no provision was made for medical care, while in the majority it was limited to from 2 weeks

to 30 days and the cost from \$25 to \$50. It was some time before it was realized that much depended upon the adequacy of medical care and there was a consequent rush to increase the amount of such care until today nearly half of the jurisdictions place practically no limit on the time and money granted for this purpose.

Today it has become evident that every phase of the administration of compensation rests for its success upon the skill of physicians and surgeons. Even the prevention of accidents is dependent upon mental and physical examinations, placement, treatment, etc.

Despite this, there is only one state in which the law provides for a physician in any official administrative capacity concerned with determining the policy of compensation and administration. Today between 70 and 80 million dollars are paid annually for the medical and hospital phases of compensation cases—a sum nearly twice as great as that paid to the physicians of Great Britain under a National Health Insurance System. In our system also there has been a tendency to introduce the most undesirable elements of commercialism into medical relations.

In some states, chains of clinics have arisen with salesmen who solicit business—for inferior service. The plant medical systems have been unduly stimulated by the profit motive of saving compensation rather than care for the patient. Recently these schemes have grown to include complete medical care, first of employees, then of their families, and finally of entire communities. "Pay-roll check-offs" have been legalized.

In all of this physicians have had little to say. It has been the work of laymen. Indeed, in some sections, physicians engaged in compensation and industrial work have lost touch and sympathy with the great body of practitioners and to some extent with the

traditions and ideals of the medical profession.

A critical point in the evolution of compensation seems approaching. Will a lay-controlled system of health insurance evolve for the industrial population, or a system of ethical care for workers directed adequately by the profession?

Among other industrial organizations the National Industrial Conference Board has recognized these issues. There is an immediate and urgent need for medical representatives in the administration of compensation.—*A. M. A. Bull.*, 27, 6:131-133 (June), 1932.

**Report of the Royal Commission on the Use of Radium and X-Rays in the Treatment of the Sick, etc.**—There seems to be a definite relationship between the incidence of cancer and certain occupations: (1) Work in tar, pitch, and bitumen briquettes; (2) Work in mineral oil or paraffin or in any compound, product or residue of either of these products; (3) Work in arsenic; (4) Work in X-rays and radium; (5) Work in mines, e.g., the lung affection of Saxon miners called "Bergkrankheit"; (6) Chimney sweeps' work; (7) Work in anilin dyeworks.

The specific irritants of carcinogenic agents appear to require a long time to show their effects. In some instances the action of the irritant may have disappeared long before cancer declares itself. The oil bearing shales of Scotland and the lignite of Germany are prone to develop skin affections. Mulespinners' disease (epithelioma of the scrotum) is attributed to soaking of the parts by lubricating oils thrown off from the spinners. Approximately 2.5 per 1,000 of mulespinners develop this disease.

Arsenic cancer occurs in the manufacture of "sheepdip" and among tin smelters. X-ray cancer is, of course, well known. "Bergkrankheit" of Erze-

birge, Saxony, which causes malignant tumors of the lungs, has been known since 1897. The dust of the mines contains bismuth, cobalt, and arsenic while the air is radio-active. The affliction lasts for years, but proves fatal as a rule in middle life.

Chimney sweeps' cancer is probably as common today as ever it was—5 or 6 deaths from it a year in England. Bituminous coal dust from the Midlands is said to be the most tumor-producing.

The fact that Hoffman found no evidence of malignant tumors as a contributory cause of death in an analysis of nearly 2,000 death certificates of lead workers in the United States is significant in the lead treatment of cancer.

Statistics show in the last few years that cancer has steadily increased its toll among industrial classes both in Canada and the United States. The increase for the year 1931 as compared to 1930 was 8 per cent for cancer of the digestive tract and peritoneum, and 6.3 per cent in cancer of the breast.—John M. Robb, Minister of Health of Ontario, *et al.*, Legislative Assembly of Ontario, *Sessional Paper No. 41*, 1932: 171 pp. (see pp. 137-138). E. R. H.

**Physiological Response to Breathing Hot Air**—When subjects sitting at rest in a cool environment breathe hot moist air, the limit of tolerance lies between 140° and 150° F. (wet bulb). When doing work, the tolerance limit falls between 130° and 140° F. (wet bulb).

The local effects noticed are a transient sensation of burning in mouth and throat and reddening of palate and throat. With those at rest, there is an increase with some irregularity in the respiration rate. With those doing work, sweating is noticeably greater when the wet bulb temperature of the inspired air is above body temperature.

The limits of tolerance for subjects at rest and breathing hot dry air lie be-

tween 270 and 367° F. (dry bulb); corresponding limits for those doing work lie between 200 and 220° F. (dry bulb).

The local effects of breathing hot dry air are extreme dryness of mouth and throat with a slight sensation of burning in some subjects, frequent coughing, and slight reddening of palate and throat.

No general effects were observed as a result of breathing hot dry air.—Esther M. Killick, University of Leeds, *J. Hyg.*, 32, 3:332–339 (July), 1932.

E. R. H.

**Industrial Electrical Accidents in Their Neurological Aspect**—The author discusses historically and statistically the effects of the electric current upon the nervous system, including shocks, legal electrocution, and the fundamental matters of voltage, amperage, type of contact, resistance of tissues, duration of current, and the points of contacts.

The paucity of electrical injuries in Great Britain is largely due to efficient Home Office control. There are periodical inspection of apparatus, notification of accidents with subsequent inquiries, followed if necessary by prosecution.

The immediate treatment of electric shock consists in artificial respiration with the possibility of inhalation of CO<sub>2</sub> being of service. "Countershock" is discountenanced. Artificial respiration should be continued without interruptions for 4 hours, although there is no

unequivocal evidence in medical literature (with one possible exception) where life has returned after being suspended for more than ½ hour. Therefore case reports of such prolonged suspensions should be brought forward whenever they occur.—MacDonald Critchley, *J. State Med.*, 40, 8:459–470 (Aug.), 1932.  
E. R. H.

**Silicosis in the Pottery Industry**—The Home Office, Great Britain, has drafted regulations to combat as far as possible the silicosis risk inherent in the pottery industry.

The necessity for intervention is proved by the very considerable sum—£20,000—paid for compensation in 1930 in the china and earthenware industry, in respect of 98 new cases, 36 cases from the previous year, and 34 deaths. The regulations in question, known as the Draft Pottery (Silicosis) Regulations, extend the wide-reaching Code covering the manufacture and decoration of pottery, but include also premises in which flint is ground. They require the provision of effective exhaust ventilation for all dusty processes, a large number of which receive specific mention, with a concession consisting in permission to effect the work as an alternative by wet methods. The recognition of the use of a water or steam spray as an alternative to exhaust ventilation is, it is remarked, in contradiction to the view expressed at the Silicosis Conference at Johannesburg, where exhaust draught and the use of water was advocated. Cleaning by vacuum is permitted during working hours, and the Code is in general based on the dictates of common sense.

## FOOD AND NUTRITION

### The Value of Salmon Oil in the Treatment of Infantile Rickets— The authors summarize their work as follows:

Thirteen children with active rickets have been treated with salmon oil, and the response to treatment, as shown by clinical examinations, roentgenograms and determinations of blood calcium and phosphorus, has been recorded at intervals of 1 or 2 weeks. Oil was used which had been prepared from the waste products of three species of salmon, the Pink or Humpback, the Chinook or King, and the Sockeye or Red.

The oil was given in doses of from 10 to 20 c.c. a day, the average being 13.8 c.c. It was well taken and well tolerated by all thirteen children.

Response to treatment as shown by roentgenographic and blood studies was very prompt, and advanced healing was brought about in from 3 to 9 weeks.

Of the 6 children whose blood was studied after from 6 to 8 days of treatment, 5 showed definite increase in the serum calcium or serum phosphorus or both; 2 reached the normal level by the end of the first week, 3 by the end of the second week. Three children who were reexamined for the first time after 2 weeks' treatment showed a return in serum calcium and phosphorus to the normal level. Only 1 child showed a greater delay in response to treatment.

Roentgenographic evidence of response to treatment was equally prompt, 7 children showing the fresh lime salt deposits in 1 week, and 5 others in 2 weeks. One child did not show fresh deposits until the end of 3 weeks. Craniotables improved rapidly under treatment with salmon oil. Biologic assays for vitamins A and D were made of the three samples of salmon oil used. They showed that the Sockeye and Chinook oils were nearly equal in vitamin A potency to a composite sample made from nineteen medicinal cod liver oils, and that Pink oil was distinctly inferior in vitamin A potency. The Sockeye and Pink oils contained twice as much vitamin D as the cod liver oil composite, and the Chinook oil about 50 per cent more than the same sample of cod liver oil.

There is a potential supply of 1,000,000 gallons of salmon oil available through the salmon canning industries of the Pacific

states and Alaska. Approximately three-fourths of this would come from the species of salmon used in this study and shown to be potent in the treatment of rickets. About 370,000 gallons would come from the species of red salmon known to be high in vitamin A as well as vitamin D. The production at low cost of such a quantity of salmon oil would be of special value at this time, when the nutrition of many infants and children is suffering from lack of proper and adequate food.

Though exact comparison of the efficacy of salmon oil in the treatment of infantile rickets with that of other antirachitic agents cannot be made, it may in general be said that the salmon oil used in the present study was probably a more potent antirachitic agent than the average cod liver oil and compared very favorably in the rapidity of its action with viosterol. Like cod liver oil, salmon oil, especially that from the more highly colored species, has the advantage of providing vitamin A in addition to vitamin D. It also provides an apparently easily digested fat, and from the limited experience of this investigation would seem to be well taken and well tolerated.—

Martha M. Eliot, E. M. Nelson, Susan P. Souther and M. Katherine Cary, *J.A.M.A.* 99:1075 (Sept. 24), 1932.

**A Study of the Milk, Blood, and Excreta of Cows Fed Moderate and Excessive Amounts of Irradiated Yeast or Ergosterol**—The effective incorporation of vitamin D in milk, either through the feeding of irradiated yeast or irradiated ergosterol having been demonstrated, this work extends the study by feeding excessive therapeutic and toxic amounts of both of these substances, as well as undertaking to determine the effect of such doses on the cows.

Incidentally, it was found that the milk most satisfactory from the clinical standpoint was that from cows receiving 60,000 and 90,000 vitamin D units daily in the form of irradiated yeast.

This yeast is rich in vitamin B, each cow receiving about 3,500 units daily. It was found that the vitamin B in the milk was not increased by this procedure.

Moderate supplements either of irradiated ergosterol or irradiated yeast do not change the phosphorus or calcium concentration of the milk or cream. Cows which received about 450,000 units by means of irradiated yeast or about 1,500,000 units through irradiated ergosterol, showed a slight rise in the calcium and serum and a marked increase in inorganic phosphate.

In this connection the breed of the cows must be taken into consideration since this factor is of importance in relation to the output of milk. For example, the figures of calcium and phosphorus are comparatively low for the milk of Holstein cows, which can probably be attributed to the fact that cows of this breed secrete a large quantity of milk. The amount of vitamin D excreted was tested on cows receiving the normal supplements of irradiated yeast (about 300 gm.). No vitamin was recovered from the urine but the bowel eliminated about 25 per cent of the vitamin D ingested.

One of the cows receiving excessive supplements of irradiated yeast was slaughtered and the liver assayed. Assuming the beef liver to contain 3 to 5 per cent of fat, the fat from this liver contained from 20 to 30 units of vitamin D per gm., or an activity greater than cod liver oil. No instance of harmful effect of feeding excessive supplements was noted, based on lack of evidence of calcification or abnormal ash content of the ribs.

To determine the effect of the breed, similar amounts of vitamin D as irradiated yeast were given to three different types of cows, one producing a large quantity of milk with low butterfat, one with low production of milk with low butterfat, and the third

with low production of milk and high butterfat. This experiment showed that the lower the production of butterfat the lower the concentration of vitamin D in the fat, and the greater daily production of milk the greater total number of units of vitamin D incorporated in the milk.

This experiment warrants the conclusion that vitamin D supplement should be given according to the percentage production basis rather than as to the individual production of cows.—A. F. Hess, R. F. Light, C. N. Frey, and J. Gross, *J. Biol. Chem.* 97:369 (Aug.), 1932.

**The Chemical Nature of Vitamin C**—Since its discovery, hexuronic acid has been recognized as strikingly similar to vitamin C. Tillmans and coworkers (*A.J.P.H.* 22:1002, Sept., 1932) showed the close relation between vitamin content and reducing power of plant substances and concluded that the reducing factor and the vitamin were identical. Zilva found certain fractions of lemon juice with a high antiscorbutic activity but low or no reducing power, as well as fractions potent in reducing power but without antiscorbutic activity, justifying his conclusion that the reducing substances and vitamin C were not identical.

The present work was undertaken to confirm a previous test by these authors pointing to the identity of the two factors. The hexuronic acid used in the test was prepared in crystalline form from suprarenal glands of the ox and was 2 years old at the time of the experiment. The amount of acid was weighed out every 8 days and dissolved in water and aliquot portions fed by means of a pipette. Previous experiments having shown that 1.5 c.c. of lemon juice is a protective dose and that this amount contains approximately 0.5 mg. of hexuronic acid, in this test 1 mg. of hexuronic acid was used to

allow for exposure to air and age of the preparation.

Compared to the animals receiving the hexuronic acid, were positive controls which received 1 c.c. of lemon juice daily and negative controls on the basal scorbutic diet. Cod liver oil (0.5 c.c.) was given to each test animal per week. No scurvy was found in the animals receiving hexuronic acid on an average 90-day test. The animals receiving 1 c.c. of lemon juice showed some scurvy and those on the basal diet were markedly scorbutic. All of the negative controls died within 20 to 34 days. The animals receiving hexuronic acid showed normal growth and weight curves compared to those of the controls on lemon juice.

Since it is assumed that animals protected from scurvy for 90 days will remain so indefinitely, these authors conclude that vitamin C is a single substance identical with hexuronic acid.—Joseph Louis Svrbely and Albert Szent-Györgyi, *Biochem. J.* 26: 865, 1932.

**Vitamin C Content of Sheep-Liver: With Observations on the Effects of Freezing and Storage—**Aqueous extracts of sheep-liver were prepared and administered to guinea pigs to determine the antiscorbutic activity. Two methods were employed—(1) curative action on guinea pigs of graded doses of the extract in comparison with that of cabbage; (2) determination of the smallest amount of extract added daily to the basal diet necessary to prevent histological scorbutic changes in the teeth of normal guinea pigs.

In the first experiment, the animals were fed on a scorbutic basal diet of Sussex ground oats, 3,600 gm., bran 400 gm., dried egg-yolk 200 gm., and 1 per cent of cod liver oil was added daily. At the onset of scurvy and cessation of growth, daily doses of 10 c.c. and 5 c.c.

of liver extract were administered. For comparison, two other groups of animals were given 1 gm. and 0.5 gm. cabbage per day respectively, and in addition 5 c.c. autoclaved liver extract.

Control animals received (1) a fully curative dose of 5 gm. cabbage in addition to the basal diet; (2) basal scorbutic diet only. The animals were killed on the 14th day and histological examination made of the teeth and ribs. It was found that 5 c.c. of the extract compared closely with 1 gm. of cabbage, while, by the second method, the minimum protective dose lay between 5 and 10 c.c. of the extract.

Comparisons were made of the vitamin C content of (1) fresh sheep liver, (2) liver frozen at an average temperature of  $-19^{\circ}$  stored for 6 days and then thawed, and (3) liver frozen at an average temperature of  $-19^{\circ}$  and stored at this temperature for 6 months. There was a definite loss of antiscorbutic activity from liver stored at  $-19^{\circ}$  for 6 days and then thawed, 10 c.c. of the extract being insufficient to prevent histological changes in the teeth. The loss after freezing for 6 days is much less than that observed in the liver stored at  $-19^{\circ}$  for 6 months, 5 c.c. of the aqueous extract of the former being equal in effect to 10 c.c. of the latter.—Judith Isobel Mills, *Biochem. J.* 26:704, 1932.

**The Relation of Bovine Mastitis to Human Infection—**The common disorders incident to lactation in the milk secreting organ of the bovine are analogous to those in the human with certain differences. In human cases of mastitis, the staphylococcus is said to be the usual invading organism, while the streptococcus is less frequently associated with this condition. The reverse seems to be true in bovine mastitis.

In New York State nearly half the cases of all diseases which have occurred

in some 100 milk-borne outbreaks during 15 years have been associated with 10 septic sore throat epidemics. Six of these epidemics have been traced to herds in which cases of mastitis were found. In the more recent epidemics hemolytic streptococci were found which closely resembled organisms isolated from human cases. It is suggested that organisms from human sources are primarily responsible for all the epidemics of septic sore throat and scarlet fever in which mastitis is a factor.

Since January 1, 1924, in New York State there have been six outbreaks of gastroenteritis totaling 357 cases traced to the use of raw milk from cows suffering from mastitis. The types of streptococci which are the common incitants of bovine mastitis apparently are not infective for man, but when present in milk in large numbers, with their toxins, may be responsible for severe toxic disturbances, especially in children.

Bovine mastitis is a major problem in prevention of milk-borne infection.

Organisms of animal or human origin, pathogenic for man, such as the tubercle bacilli, *Brucella abortus*, and hemolytic streptococci, may be present in diseased udders. Udders infected with *Brucella abortus* may excrete the organisms during the life of the animal. Agglutination and complement fixation tests on milk from infected and uninfected quarters have given positive results and negative results respectively. Agglutinating power in the blood may be due to infection localized in the udder.

The author concludes that pasteurization is the only practical safeguard.—Paul B. Brooks, *J. Prev. Med.* 6:111 (Mar.), 1932.

**The Influence of Diet on Caries in Children's Teeth**—This is a preliminary report of a long-time investiga-

tion conducted upon about 400 children in three institutions to determine the effect of additions of vitamins A and D to the customary diet on the teeth during and after development.

The general plan followed consisted in adding to the diet of all of the children in one institution cod liver oil, in another treacle (molasses), and in another olive oil. At a later stage the children in the third institutions were divided into two groups, one of which received untreated olive oil and the other the same quantity of olive oil to which radiostol (irradiated ergosterol) had been added. Quantities of the various supplements were adjusted to the ages of the children.

Each child was given a detailed dental examination at intervals of 6 months. The present report deals only with the number of erupted teeth and the presence and extent of caries in the teeth erupted at the beginning of the investigation. A period of 2 years was covered in the first part of the investigation and 1½ years in the comparison of olive oil with and without vitamin D.

The data which were treated statistically showed that in the groups of children, numbering from 65 to 86, in the comparison of cod liver oil, treacle, and olive oil, the progress of caries in the permanent teeth was significantly retarded in those receiving cod liver oil as compared with those receiving the other two supplements. The increase in caries in the vitamin group during the period, whether measured by incidence or extent, was only about one-third that in the other two groups. In the two groups of children, numbering 82 and 79, respectively, receiving olive oil alone and supplemented with vitamin D, the progress of caries in the permanent teeth was also significantly retarded in the vitamin group. With suitable allowance for the shorter time there seemed to be no appreciable difference in the rate of increase of caries

in the group receiving cod liver oil (vitamins A and D) and radiostol (vitamin D).

These findings are thought to justify the conclusion that the potent factor in retarding the development of caries in

fully, or nearly fully, calcified teeth is vitamin D.—N. G. Bennett *et al.*, Great Britain Med. Res. Council, *Spec. Rep. Ser. No. 159*, 1931, p. 19, figs. 3). Abstract *Exper. Sta. Rec.*, 67:341 (Sept.), 1932.

## CHILD HYGIENE

### TUBERCULOSIS IN CHILDHOOD

THE prevention of tuberculosis continues to be one of the major problems of public health. At present considerable attention is being focused on childhood tuberculosis. The principal sources and modes of infection have become well known during the 50 years since the discovery of the tubercle bacillus by Koch. An enormous amount of study has been devoted to problems connected with the origin, spread, and prevention of the disease. Since measures for its prevention have been applied more intensively, there has been a gradual reduction in the death rate from tuberculosis, more marked in the younger age groups. While this is true, it still remains one of the important communicable diseases affecting children, especially in the preschool age and during adolescence. While the death rate during the preschool period is relatively low, the rate of infectivity is very high. A great deal of data has been accumulated on this point since we have been applying systematically the tuberculin test and the X-ray.

On the other hand, while there has been a diminution in the tuberculosis death rate between 15 and 25 years of age, this has been most marked in the male. Females between these ages have not shown this decided decrease. This was clearly pointed out by Howard Whipple Green in his *Graphic Analysis of the Trends in the Tuberculosis Death-Rate*, which report was pub-

lished in March, 1927. Since that time a number of other studies have confirmed his observations. Recent attempts have been made to determine the exact cause for this lag in the reduction of the tuberculosis death rate among young women.

Kendall Emerson, in a summary of the outstanding facts concerning tuberculosis<sup>1</sup> says that:

1. One out of every 5 persons who die between the ages of 15 and 45 dies of tuberculosis.
2. One out of every 3 young women who die between the ages of 15 and 30 dies of tuberculosis.
3. Tuberculosis kills more children under 21 than any other communicable disease.
4. It is estimated that 2,000,000 children have been infected with the germs of tuberculosis—and it is from these children that most of the active cases will come in later years.

The foci of tuberculous infection are mainly two, the tuberculous individual disseminating the organisms largely from the respiratory tract, and the tuberculous cow contributing the organisms directly through milk from diseased udders or indirectly from milk infected by the tubercle bacilli lodged in dust from infected excreta. Undoubtedly bovine infection is becoming less and less common in this country, as pasteurization and boiling of the milk before giving to children have become more widespread.

The campaigns for the eradication of

tuberculosis among cattle and the more rigid application of pasteurization undoubtedly have been responsible largely for the reduction in the amount of bovine infection. There is no question that tuberculosis of the bones and joints and of the cervical lymph glands has decreased markedly in this country within the last 25 or 30 years. However, we still have reports from other countries, notably certain parts of Canada, Great Britain, and Scotland, which still show a considerable proportion of children infected with bovine tuberculosis. We, therefore, should not cease in our efforts to eradicate the tubercle bacillus in cattle while we are engaged at the same time in a more active struggle against infection of children from tuberculous contacts in their home environment. Kendall Emerson further warns us that "Optimistic prophecies about the early eradication of the disease are not only a disservice to the community, but are not borne out by facts."

A recent study of tuberculosis mortality among young women<sup>2</sup> confirms former observations and also brings out some very interesting correlations.

This failure of the tuberculosis mortality among young females to keep pace with the decline in the general tuberculosis death rate, together with the fact that the peak of tuberculosis mortality for both sexes and all ages up to 65 years falls among girls from 15 to 25, is probably one of the most striking points in any study of tuberculosis deaths in the United States. Its importance is emphasized further by the fact that between the ages of 15 and 25 years the death rate among young women ranges from 50 to 90 per cent higher than among young men of the same age.

However, the increasing disparity between the male and female rates is not, as is sometimes believed, a reflection of rising death rate among young women. . . . The death rate among females from 15 to 19 years of age has decreased by 46 per cent since 1900, and for young women 20 to 24 years of age there has been a decline of 53 per cent. . . .

As far back as we have any reliable information (1900), tuberculosis has been a

serious problem among young women. If we should say that tuberculosis among all groups of the population *except young women* is a *decreasingly* serious problem, we should be stating the present situation much more accurately than we do when we speak of its *increasing* seriousness among young women. The problem itself is not growing and has not been newly generated; it simply appears larger and clearer as the importance of its background fades.

The main conclusions of Miss Nicholson in this study, while not agreeing entirely with similar studies, still bring out in contrast some suggestive points which should be investigated further.

On the whole, it is the opinion of this investigator that the problem of tuberculosis among the young women of Detroit during 1930 was primarily a problem of the child-bearing period and of the period during which physical development constituted a more or less consistent strain upon the strength and general health of the young woman. The importance of such living habits as a lack of sufficient sleep, and such environmental factors as broken homes, is noticeable but seems secondary to the other elements in the situation.

Only by such studies can we hope to arrive at a complete knowledge of this protean disease.

The study by Howard Whipple Green of the situation in Cleveland does not agree with certain of the findings in Detroit. In his *Tuberculosis and Economic Strata, Cleveland's Five-City Area, 1928-1931*, Green finds enormous differences exist in the tuberculosis death rates and case rates in the various economic areas.

The age specific death rates by sex for the low and high areas are worthy of study. In the low area the male rate is quite similar to the female rate to age 25 after which time the male rate is considerably higher. In the high area, however, these rates are quite similar throughout, both being much lower at all ages than is the case in the low area. The rates for the colored population in the low area are quite different from the rates for the white population and much higher.

His general conclusion is that "not only tuberculosis but other ills of

humanity are accentuated by economic status."

An excellent report on Tuberculosis Service for Children by Dr. Margaret Witter Barnard in the October, 1932, issue of the *Milbank Memorial Fund Quarterly Bulletin* states:

Our increasing knowledge of tuberculosis in children is opening up a highly specialized field. . . .

In order effectively to safeguard the tuberculous child, it is necessary to know whether or not there are other cases of tuberculosis in the family group and how great the risk of further exposure to infection will be if the child remains in the group. The complexity of family situations in cases of tuberculosis in children may be graphically illustrated by charts such as those given. . . . These are based on data gathered in the tuberculosis clinic services for adults and children at the Bellevue-Yorkville Health Center over a period of years. . . .

If tuberculous children are to be cared for intelligently, not only must the clinic view the problem as a family situation but the family must also be educated to a similar viewpoint. In this manner only may the coöperation of the family be secured.

The four objectives of a tuberculosis service for children are stated as follows:

1. To screen out the children with tuberculosis and to determine the significance of their lesions.
2. To plan adequate care for them, including finding the source of their infection and breaking the contact.
3. To educate the families to regard tuberculosis as a family problem and to help them make adequate plans to deal with it.
4. So to record and assemble all data that they will be available for use in further studies of the general problem.

The children's tuberculosis clinic should offer diagnostic service to children from several sources. Child contacts of patients in the adult tuberculosis service should be referred as a matter of routine to the children's service for examination. Not only is it of importance to detect all tuberculosis in this group, but also through these examinations to gain a picture of the general health problems with which the family must deal. Social agencies, school physicians and nurses will wish to refer to this clinic children who present suspicious symptoms or history of

exposure. And the child hygiene services will constantly use this special service for consultation. Routine tuberculin tests, followed by X-ray examination of the positive reactors, in the infant and preschool groups will screen out a number of children who should be referred for further consultation on diagnosis and care. Although a well organized and integrated tuberculosis service for children is costly, it will show very definite results both in controlling the disease in children and as a method for case finding among the adult contacts. When funds are limited, experience indicates that two groups showing the most significant lesions, needing the most intensive care, and giving the best results are the preschool and the adolescent.

The important diagnostic procedures which should be carefully standardized and of a high technical quality are:

1. Complete pediatric examination
2. Intradermal tuberculin test
3. Flat and oblique X-ray

On these data, in conjunction with a careful history and an understanding of the home conditions of the child, will be based the disposition of the case. Because it is impossible to separate tuberculosis in a child from his general condition, the physician in charge of this service should be a competent pediatrician.

Dr. Barnard states clearly that the preschool and adolescent groups present an extremely difficult problem.

Since it is in them rather than in the 6 to 12 year old group that significant lesions requiring institutional care seem to be found most frequently.

She stresses the fact that

Experience shows that children of the school age group handle tuberculous lesions remarkably well and that intelligent home care is usually sufficient.

This fact is brought out also by Dr. W. P. Shepard in a discussion of the contribution which Lymanhurst has made to the tuberculosis movement,<sup>2</sup> especially from the standpoint of a public health problem. He quotes Homer Folks as saying many years ago that the main objectives of the antituberculosis movement of case finding, treatment, control of spread, and education

are the ones which we are still employing today and that practically no new major item has been added to the program. However, a great development has taken place in the application of the various technics which have been elaborated for the discovery of tuberculosis. In other words, there have been no new objectives, but numerous new methods of obtaining the objectives.

The most important development has been the recognition of the tuberculosis movement as a general public health movement. Dr. Shepard feels that one of the outstanding contributions of Lymanhurst to the antituberculosis movement was the successful demonstration of what is needed and what is possible to modify the public school curriculum to meet the health needs of the school child. He points out that

In the tuberculosis field alone the adoption of this principle is markedly changing our administrative procedure. It completes, according to our present knowledge, the circle of tuberculosis protection thrown around the individual. Ideally, now, we have a home free from contact. Missing that, the child with early infection that threatens disease is given special care in the health-school. Missing that, the preventorium is available. Missing that, the sanatorium is available for cure.

Dr. Shepard mentions Myers' pronouncement<sup>4</sup> on "the necessity of applying the recognized principles of contagious disease control to tuberculosis." Myers has cited many preventable tragedies, particularly among nurses and medical students due to the neglect of well known methods of disease control. He believes that "tuberculous infection is decreasing decidedly, some rural communities showing less than 30 per cent positive reactors among their young." He believes further that "this reduction in the incident of tuberculous infection is progressive and the natural result of elimination of tuberculous milk-cows, and extensive isolation of the tuberculous human being." This, of course, places the problem largely in the hands of the epidemiologist and the clinician; although other social and economic factors may contribute to its solution.

# PUBLIC HEALTH NURSING\*

A FEW GLEANINGS FROM THE RECENT ANNUAL MEETING OF THE AMERICAN  
PUBLIC HEALTH ASSOCIATION, HELD IN WASHINGTON, D. C.  
(FROM A PUBLIC HEALTH NURSE'S NOTEBOOK)

## *School Health*

In a recent study by Dr. Franzen of the American Child Health Association, only 50 per cent of children 7 or more per cent underweight were actually malnourished. This is only a little worse than bare chance.

Out of 100 cases of malnourishment only 4 were detected by the teacher. Height-weight tables detect only 12 per cent of the malnourished.

Teachers were only 13 per cent efficient in detecting dental defects, and only 15 per cent efficient in detecting severe vision defects.

The teacher's usefulness in school health work has not been exploited—her knowledge about the health of children needs to be used more by health workers. Where the school nurse has discussed a child with his teacher beforehand her home visit is much more effective. Closer coöperation between teacher and nurse improves school health work.

Dr. Phair of Toronto found in an extensive survey that the school nursing staff did not materially aid the control of communicable disease in a community, and that school health services in which public health nurses worked alone appeared to be just as effective as when the services were headed up by school physicians.

## *Child Welfare*

Dr. Phair, in his survey, found that few of the agencies carrying on child hygiene work kept good records. Their ideas of the purposes of their service

were vague; the medical and health services were not intimate enough. For the most part, the measurement of the efficiency of the child hygiene program was the number of children attending the well baby clinics. No one knew how many babies under 11 months were regularly consulting their family physicians.

## *Tuberculosis*

Dr. Atwater of Cattaraugus County found only 1 case of manifest tuberculosis among 1,308 rural children. He recommends for a tuberculosis program in a rural area the examination of contacts of diagnosed cases and the routine examination of high school students, preferably seniors.

Violet Hodgson, R.N., said the major step for the public health nurse was the finding of adult tuberculosis cases, and one good measurement of her effectiveness was her ability to get good case histories.

Dr. Winslow of New Haven said that 40 years ago practically everyone had been infected with tuberculosis and the physiological or personal hygiene attack was necessary to help one keep up his resistance. Now since it is found that in rural communities, at least, everyone has not yet got the tuberculosis germ, the bacteriological emphasis needs to be put on tuberculosis control, that is, the prevention of the spread of the disease.

E. F. M.

WHEN PUBLIC HEALTH NURSES  
WRITE PAPERS

Sitting through a season of innumerable annual meetings of various health

\* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

and nursing organizations at which public health nurses have read papers, puts one in a position to make some observations on these papers and their failure or effectiveness in creating the interested attention of the listeners.

There are four kinds of writing—descriptive, narrative, argument, and exposition. "Entertainment is primarily the aim of narration and description; instruction is the main purpose of argument and exposition." Most professional papers are expository—they explain something—they impartially unfold a generalization to the understanding of the listener.

On its structural side a successful paper is dependent upon careful selection and clear arrangement of material and adequate amplification. It is usually on this last feature that public health nurses fall down in their papers.

The most important method of amplification in expository writing is *reducing generals to particulars*.

Exposition deals largely with the abstract and the general. The full meaning of the general and the abstract is usually not clear, and clearness is the *sine qua non* of expository writing. Hence the writer must take pains to avoid excessive abstraction by giving the specific details upon which his generalizations are based. General facts must be amplified by enumeration of particulars enough to make conclusive ground for the assertion of it; general principles must be amplified by instances and examples in order to make clear the character of them. It is a good rule for expository writing, and one that the young writer will do well to adopt literally, to follow every general statement with particulars and details, with specific examples or concrete illustrations, or comparisons and analogies with what is known and familiar. "Abstractions produce very little or no effect until translated into concrete," says Lamont. "If the writer does not translate them the reader must; and this task makes hard reading." Concreteness, therefore, is very important in expository writing, both for clearness and interest.

Public health nurses can draw from such a wealth of interesting incidences

in their experience that they never should have any difficulty in backing up any generalization with a concrete illustration. A public health nurse who had been particularly effective in assisting the state sanitary engineer to get people in her county to see the need of a sewage plant and sanitary privies in her county seat and several other towns in her county which had been having a consistently high typhoid fever morbidity and mortality rate, was asked to be on a state health officers' annual meeting program to tell how she did it. Instead of giving concrete incidences of problems she encountered and overcame, she spent the whole time telling what she would do if she ever started over in a new county—how she would work with the medical profession, develop group leadership among various clubs, etc. Not one point that was made could be remembered from her paper. She lost a valuable opportunity and actually bored her listeners.

Elma Rood, of Detroit, who read a paper on "The Part the Laity Plays in a Rural Child Health Program" at the recent American Public Health Association Meeting in Washington, D. C., illustrated this point on the positive side. Toward the end of her paper she told about Pumpkin Creek's loan closet, how the children in Sleepy Hollow were transported to the dental clinic at a neighboring center, how the preschool children with the mothers were given a "party" at an isolated rural school, and while there were given complete physical examinations. Long after the generalities in this paper are forgotten those who heard it will remember these concrete examples of effectiveness of the child health program—and they will remember the general principles involved by deductions from them.

Public health nurses are not the only ones who fail in amplification, but that's another story.—Maurice A. Fulton, *Expository Writing*, Macmillan Co.,

1926, pp. XIII, XV, XVII, XX, XXVII, XXXIV; Elma Rood, Participation of Lay People in the Promotion of a Rural Child Health Program, *A.J.P.H.*, XXII, 10:1030-1032 (Oct.), 1932.

#### NURSE FELLOWS OF THE A.P.H.A.

Public health nurses have often been criticized for taking too narrow a view of public health, of thinking their own contributions to a community paramount, to the exclusion of all the other public health workers. They are closely allied with the whole nursing group through membership in district and state nursing associations and in the American Nurses' Association; they are members (we hope) of their special group, the National Organization for Public Health Nursing, but these affiliations are not enough. Public health nurses need to be tied up in some way with the broader field of public health of which they are only a part, by membership in the American Public Health Association, the oldest unofficial public health organization in America. This Association has 9 active sections besides that on Public Health Nursing, and reading the official magazine of the Association and attendance at its annual meeting offer unparalleled opportunities to a public health nurse to get a broad perspective of the whole field of public health.

Since the objective of the public health nurse is "the satisfactory adaptation of the individual to an environ-

ment that makes health possible" how can she do without the contributions of the different sections of the A.P.H.A.—Health Officers, Laboratory, Vital Statistics, Public Health Engineering, Industrial Hygiene, Food and Nutrition, Child Hygiene, Epidemiology, and Public Health Education? She needs to belong to the Public Health Nursing Section of this organization to insure the integration of public health nursing with these other branches of public health.

There are already around 500 nurse members of the A.P.H.A. Public Health Nursing Section, and out of some 15,000 public health nurses in this country there should be more. However, there are very few Fellows in the Public Health Nursing Section. Public health nurse executives who are all more or less responsible for staff education programs should all be Fellows. The section officers must be Fellows, and how can they be truly representative of the best in public health nursing in this country if there is a meager number of Fellows to choose from? Only a Fellow, too, can cast a vote at the annual meeting, and that means something if public health nursing is to take its place as part of a general public health program. Write to the American Public Health Association, 450 Seventh Avenue, New York, for membership or fellowship blanks.

Those in the Section who are already Fellows would do well to think about a Life Membership.

E. F. M.

## EDUCATION AND PUBLICITY\*

**The Health Education Institute—**The first response to the announcement was a surprise to all concerned. The number and the representative character of those enrolled gave evidence of a high grade personnel engaged in health education activities. We now *know* that the most experienced of the workers have that will to learn.

Extracts from the factual material will be given in this department in future issues.

**A Question of Ventilation—**Does the practicability of ventilation need ventilating?

Can health educators make much progress without attention being given to methods for control of heating and ventilating homes, offices and meeting places?

What is the use of talking about 68° when so many people are uncomfortably cold at that temperature?

Have any of the fresh-air workers thought out the practical problems and how to meet them?

This year a lot of people will not be over-heated in their homes. Can we help meet that set of practical problems by offering truly practical advice?

**Education as It Is—**Education of the individual grows out of contacts with people and things, with ideas and information.

Some of it is planned and directed, but much of it is casual and incidental to life.

In the Health Education Institute we were concerned with what touches young people and adults apart from the

sharply defined and specific group found in a high school or college class.

Sometimes we teach under conditions similar to those of the classroom when we can carry out a course of study or other health project in a club, factory, etc.

**It's a Long, Long Trail—**In a letter received by the North Carolina Board of Health, a nurse

. . . describing the insanitary condition and actual danger resulting therefrom in a number of the smaller schools in the section of the state she was at work in, she concluded with: "To tell the truth, the teachers are just beginning to understand sanitation. It is really the gradual process of education."

It is a knowledge of this fact and especially the fact that it takes a long time for the masses of the people to receive and absorb sound information on these questions that makes it so important at the present time that no ground be lost which has been attained toward this end.—

*Health Bulletin*, North Carolina Board of Health. Oct., 1932.

**Community Health Organization**—"Education of the public in the principles of healthful living and disease prevention is a most important function of the health department." These words introduce the chapter on "Popular Health Instruction" in *Community Health Organization*, the revised edition of the manual of administration and procedure for cities. In a dozen pages we have a concise summary of the essentials in program planning and execution which serves as a guide to a critical review of the present health education work of a department, as well as a framework for an adequate program.

A significant detail is the reminder

\* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

that "an adequate popular health instruction service calls for a trained technician with a salary commensurate with the responsibility and training demanded."

We wish that more had been said about the position of leadership which the department should hold in cities where various agencies are doing health education, and how the department might effectively coördinate all local activities in this field with economy and increased effectiveness. The chapter on "Voluntary Health Service" has several paragraphs on this important subject.

Every staff member of a health department or a private health agency should read the entire book for the perspective of the whole field. The book is edited by Ira V. Hiscock, and published by Commonwealth Fund, New York. \$2.00.

**When Doctors Advertise**—"A preliminary review of recent advertising concerning medical service and public health, conducted by county medical societies, public health agencies, hospitals, clinics, and business organizations," is *Medical Advertising*, by Mary Ross, issued by Julius Rosenwald Fund, Chicago. 72 pages. Free.

"Advertising may be taken to mean the use of a certain amount of purchased space or time to inform the public as to something which the purchaser believes the public needs or may desire." Much interesting information is given about advertising experiments by medical and dental societies. Advertising in periodicals by a group of ethical business firms to emphasize the services of the medical profession is described.

The chapters devoted to public health agencies have almost nothing to do with "advertising" and less with paid advertising, except in the case of the Public Health Institute of Chicago and

the Life Extension Institute of New York. The picture of "advertising" is blurred by the inclusion of non-advertising forms of health education and publicity. A smaller pamphlet would have been more useful.

The reader of the report should bear in mind the wide difference between advertising to promote use of the services of physicians, and advertising for the promotion of health habits or maintenance of health agencies; and the different significance of paid space and of contributed advertising space in newspapers or magazines.

**A Use For Your Ideas**—Ideas for cartoons on public health can be passed on to some of the syndicates supplying cartoons to newspapers. Ideas for newspaper and magazine articles have a chance for hopeful consideration. Any form of factual or illustrative material which might be used by writers is earnestly requested.

Please send any of the above mentioned material to Paul Komora, National Committee for Mental Hygiene, 450 7th Ave., New York. Mr. Komora is chairman of the Health Section of the United Educational Program. This is the committee responsible for the public health numbers of the bulletin series, "Behind the Front Lines" mentioned elsewhere.

**"Fighting" For Health Department Budgets**—Depression effects on health department budgets were treated in a general session at the Washington meeting of the A.P.H.A. Several speakers referred mildly to the need of interpretation or explanation. A strong appeal was made for a "fighting" attitude toward budget cuts. One state health officer related his successful dealings with several political leaders. No one explained how to "fight" against budget cuts. No one suggested that it was more than a one-man job.

There was no indication that the maintenance of the health department is a community job, nor that the health officer might and should share with the citizenry the responsibility of meeting budget reductions.

What can be said for a health department? Almost anyone will grant that it is important, very important. Most people know about many of its activities. But what can be said in favor of its budget, even in normal times? What ideas or arguments can be offered? What evidences of its value can be offered?

How can the community be led to accept responsibility for health department maintenance? What particular groups should be cultivated and informed? What is desirable and practicable in the way of a council, committee, or other organization relationships?

The recreation and character-building agencies faced a similar problem last winter. A committee was formed by the Social Work Publicity Council. This committee and several subcommittees did some hard work. They dug into their philosophies and their publicity in search of what they had a right to claim would be convincing. They analyzed doubts and objections and stated their answers. They searched for the best statements made by various authorities.

They put this material into form for a meeting last spring, and then issued a pamphlet for wide use by those who are raising funds and explaining work for young people to local communities.

Should we do something similar for public health?

**How Do You Use Them?**—The series of bulletins of material for producing publicity, "Behind the Front Lines," has gone to all community chests. Some national agencies have

sent their special bulletin to locals in their field. Ask your national, or send 10 cents for single copies, \$1.00 for the series, to Association of Community Chests and Councils, 420 Lexington Ave., New York. Titles: Public Health Nursing, Tuberculosis, Hospitals, Nutrition, Child Health, Social Hygiene, Mental Hygiene, Recreation and Character Building, Transients, Social Case Work, Emergency Relief, Protective Measures for Children.

How have you, or the chest, or any other agency used any of the material in those bulletins? Please send samples. Please also send suggestions for preparing better material for local use.

**All Should Know the Facts—**  
Says Dr. John Sundwall, University of Michigan:

In addition to specialists in adult and child health education, all public health work must be permeated with the idea, function, scope, and importance of public health education. Today it is just as important for all public health workers to have an appreciation for and a general working knowledge of public health education as it is for them to know about water filtration, sewage treatment, nutrition, mental hygiene, and related subjects.

Hence public health education not only requires experts, but it must become one of the working tools for all public health workers. Already attention has been called to the importance of adequate training, on the part of the public health educator, in those basic sciences which acquaint one with the structure, functions, and care of the human body. The first principle in all public health education is knowledge of the facts involved in the promotion of health and the prevention and control of communicable diseases. Far too much of our public health education of today includes opinions and empiricisms. This is due largely to our innate tendency to react emotionally toward our human make-ups, whether in order or out of order. What we feel to be a good health practice we are prone to pass along as a scientific dictum. Moreover, there is that emotional proclivity to adopt and follow the single-track mind in matters pertaining to

health. Hence fads and hobbies may permeate health practices and public health education.

The public health educator should and must know the facts—not only the established facts, but also the new facts which are contributed almost daily through research and investigation. The second principle in health education is to know how to present these facts to the public—adult and child—and to present them.—

In "Public Health Education: The Functions of the University and the Private Foundation." *Public Health Reports*, Washington. Oct. 7, 1932.

Includes, what the university does; "The Functions of Nonofficial Health Agencies"; "Official Versus Nonofficial Health Agencies." All good for all of us to read all of it.

#### MOTION PICTURES

Health Officer Frank Osborne, East Orange, N. J., with the active collaboration of two board members has a motion picture presentation of the department activities. On narrow film this picture was quite inexpensive to produce and promises wide usefulness. An extensive schedule of local showings has been worked out.

At Washington the Metropolitan Life Insurance Company presented a new talking picture which will be described next month.

*The American Journal of Cancer* is offering, without cost, a series of motion picture films on cancer for showing before medical groups. The films now ready for distribution are "Cancer of the Skin," based on material gathered by Dr. Joseph Colt Bloodgood and Dr. Charles F. Gerschicter of Johns Hopkins Hospital, and one

showing "Technical Methods of Cancer Research," taken at the Institute of Cancer Research, Columbia University. The films are obtainable in either 16 or 35mm widths, and are adequately titled so that no explanation is required while they are being shown. They are available for use in the United States only. Full information concerning the films can be obtained from the Motion Picture Department, *American Journal of Cancer*, 1145 Amsterdam Ave., New York, N. Y.

#### DEPRESSION

"Observations on the Depression and Public Health," by Dr. D. B. Armstrong. Reprint from *Medical Journal and Record*. How depression does not affect public health, and how it does do so. *Free*. From Metropolitan Life Insurance Co., New York.

"Depression Death Rates." Editorial. *Journal of American Medical Association*, 535 N. Dearborn St., Chicago. Oct. 15, 1932. *Free* copy in Clip Sheet for Editors. A readable interpretation usable in many ways.

*Birmingham's Health*, Jefferson County Board of Health, Birmingham, Ala., had a cover-page cartoon supplied by the Health Education Service of the A.P.H.A. illustrating "depression economy" as "one more obstacle on an up-hill road." The Health Department is a big truck loaded with boxes and bundles representing "vital statistics," "education," "clinics," and so on. Big rocks in the road are "indifference," "carelessness," "ignorance," and "delay." Beyond the rocks the truck seems stalled in heavy ruts labeled "depression economy." Sept., 1932.

## BOOKS AND REPORTS

**Nurses on Horseback**—By *Ernest Poole*. New York: Macmillan, 1932. 168 pp. Price, \$2.50.

This is a very dramatic and interesting story of the organization and work of the Frontier Nursing Service in the mountains of Kentucky. The author writes from first hand observation, having made a visit to the centers, and field trips with the nurses, and held conversations with the mountaineers. It is a story of the organization by Mrs. Mary Breckenridge of the first nursing center in 1925, and how this has grown in seven years until, "in a small central hospital and 8 outlying stations in lonely regions of the hills unreached except by mountain trails, 28 nurses with 3 supervisors serve a region covering nearly 800 square miles, in the counties of Leslie, Perry, Clay, Bell, Harlan, Knox, and Owsley."

The nurses are all trained in midwifery and public health nursing. The midwifery work is probably their outstanding service, and is in itself a pioneering field in this country. "The care of mothers and babies, though it is still their main concern, almost inevitably leads to the care of the entire family." This care includes first aid, immunization, and general health instruction for adults, infants, and children.

If to some this writing seems to be over-sentimental we must remember that the general public, for whom the book is written, likes this type of presentation. It is in no way a professional study of the service. The book is full of human interest stories which give word pictures of the characteristics and environment of the "mountaineer." In reading one follows the "Nurses on Horseback" over rough mountain trails, day and night in all

kinds of weather. Interesting illustrations add completeness to the word pictures.

All who read will enjoy this book, and we hope it may help in interpreting to the public not only the work of the "new pioneers on old frontiers" of Kentucky, but the daily work of many public health nurses who are doing pioneer services in many localities and with many types of people, nurses whose work goes unpraised and often unappreciated.

FLORENCE E. SPAULDING

**Handbook of Bacteriology**. For Students and Practitioners of Medicine—By *Joseph W. Bigger, M.D.* 3rd ed. New York: Williams & Wilkins, 1932. 459 pp. Price, \$5.00.

The first issue of this book was January, 1925, since which two editions and one reprinting have been required. The book is one of the best of its class, well written and well expressed. A criticism that can be made is that it is too devoid of history. The organisms discussed have the name of the discoverer and the date of the discovery, but little or nothing more. The discovery of the anthrax bacillus is credited to Robert Koch in 1876, yet the organism was discovered in 1849, and in 1863 experimental infection with animals was done. It is also stated under Anthrax that the serum of Sclavo is the best. The author apparently has not heard of the improved serum developed by Eichhorn at the Bureau of Animal Industry in this country, which is considerably more potent than that recommended.

Under the head of immunity, the author has given very little space to Erlich's side chain theory for which he

expresses regret. We believe that his reasons for leaving it out are sound, though we miss it and still hold the opinion that for teaching purposes it has great value. The book is well printed and illustrated.

MAZŮCK P. RAVENEL

**Labor Problems and Labor Legislation**—By *John B. Andrews, Ph.D.* (4th ed.) New York: American Association for Labor Legislation, 1932. 135 pp. Price, cloth, \$.60; paper, \$.30.

This is the fourth revised edition of a standard treatise on labor legislation. In addition to cogent material on wages, hours of labor, collective bargaining, social insurance, and law enforcement, it sets forth guiding principles to make industry reasonably safe from accidents, and workers free from preventable diseases. The book is well printed, but has no index, and some of the many illustrations seem to have been inherited from earlier editions, in fact, from very early ones. Sanitarians interested in industrial hygiene and the prevention of occupational diseases will find this booklet of interest. JAMES A. TOBEY

**Hygiene, A Textbook for College Students**—By *Florence L. Meredith, M.D.* Philadelphia: Blakiston, 1932. 802 pp. Price, \$3.50.

This book is designed as a textbook in hygiene for students of the college level. It is the second edition, which has been revised and the contents rearranged.

The text is divided into 5 parts: Part I, on the need of teaching hygiene to students of the college level; Part II, devoted to human anatomy and physiology; Part III, pathological conditions; Part IV, the various phases of personal hygiene and Part V, the discussion of mental hygiene.

Part II devotes 160 pages to anatomy and physiology. While some basic

scientific information is necessary as a foundation for teaching health, there is some question whether any such proportion of a college course in hygiene, where the major aim is that the students may understand and practice healthful living, should be given to these subjects. Over 90 pages (Part III) are devoted to discussion of disease conditions.

The bibliography is placed at the end of the book. This would be more likely to be used if placed at the end of each chapter.

Some would question the desirability of segregating anatomical, physiological, and pathological material in definite large sections in the text. A more intimate nearness of the discussion of normal conditions, and of the pathological results of errors of living, to the discussion of the prevention and cure of faulty health by right living, would seem a more interesting and usable arrangement.

Of the 802 pages of the main text, a little over one-half are devoted to the discussion of various problems of hygiene and right living.

In spite of the heavy emphasis on technical anatomy, physiology, and pathology, this is one of the few good texts on hygiene, planned for the college level. Those considering the adoption of a college-level textbook in hygiene should give this work serious consideration. CHARLES H. KEENE

**House Design, Construction and Equipment, The President's Conference on Home Building and Home Ownership.** Washington, D. C. Price, \$1.15.

This volume, published as a result of the President's Conference on Home Building and Home Ownership, covers the design, construction, and fundamental equipment of the home. The problems of the designer are to distinguish essentials from nonessentials,

to plan efficiently for the most economical use of materials, and to make the small homes attractive in their mass as well as in proportions and detail. In these problems the designer needs the coöperation and help of the builders, contractors and the manufacturers of material and equipment.

The Committee on Construction emphasized the necessity for more widespread use of the best building practices; helps to protect the home buying public against "jerry" building; and the need for search and research for new and better materials and methods. Fundamental equipment in homes of today is superior to that in those built in the past. Devices for heating, lighting, plumbing, refrigeration, and ventilation have undergone remarkable developments in the past few years. The Committee on Fundamental Equipment considered standards, location, and installation of such equipment. Its report brings together a summary of information of great use to every builder, owner, or renter, and throws light on relative values and best uses for equipment now on the market.

ARTHUR P. MILLER

**Negro Housing.** The President's Conference on Home Building and Home Ownership. Washington, D. C., 1932. *A Report of the Committee on Negro Housing. Prepared by Charles S. Johnson.* 271 pp. Price, \$1.15.

Public health opinion tends more toward considering environmental factors as being responsible for the high morbidity and mortality rates among negroes than toward the view of the existence of some peculiar racial susceptibility on the part of these people. Important among these causes is that of the widespread poor housing that affects negroes in both rural and urban centers.

The problem of housing among

negroes is complicated by that of race relations. Indeed there are few if any situations of community adjustment involving this race which are not profoundly influenced by inter-racial complexities. This makes necessary the provisions for special studies in reference to the negro if a comprehensive conception of his problems and their connections with those of other racial groups is to be secured. Recognizing this fact the President's Conference on Home Building and Home Ownership set up a committee to make special investigations and analysis of the status of negro housing. The results presented in this volume are a synthesis of facts and their influence entering into this situation. The treatment is candid, broad in conception, and informative. It marks an advancement toward a better understanding of a difficult social condition. The presentation should be of value to public health workers despite the brevity of treatment of the health of the negro and his housing (page 57). The health inferences that may be drawn from the facts are bound to impress those interested in public health.

FRANKLIN O. NICHOLS

**Growth and Development of the Child—Part III—Nutrition.** A publication of the White House Conference on Child Health and Protection. New York: Century, 1932. 532 pp. Price, \$4.00.

This book is one of the four volumes prepared by the Committee on Growth and Development of the White House Conference on Child Health and Protection. The main object of the committee was to appraise the existing knowledge of growth and development of children from conception to maturity. The present volume is an exhaustive consideration of our present-day knowledge of nutrition in relation to growth and development. The thoroughness of the investigations

which form the basis of this volume is attested by the character of the investigators who presented various phases of the subject. It is really a compendium of our present knowledge and investigations of practically every phase of nutrition. The chapter on "Optimal Growth and Nutrition" corrects many erroneous views which have been held since height and weight standards have been used extensively in the schools. Each chapter is followed by a list of up-to-date references.

RICHARD A. BOLT

*The Crisis in Hospital Finance—By Michael M. Davis and C. Rufus Rorem. Chicago: University of Chicago Press, 1932. 241 pp. Price, \$2.50.*

One might cavil at the title though hardly at the contents of this timely review of the economic progress of voluntary general hospitals towards bankruptcy. We see the progress of long time policies leading to the apex of a dilemma, the solution of which involves a lot of rationalization, hard thinking, and close figuring by the holding corporations, commonly thought of as beneficent hospital trustees, by the necessitous public, that is, patients demanding instant attention, and by the physicians who serve on organized and courtesy staffs of hospitals.

There are no better documented authors on hospital economics, and the social implications of hospital costs and financial resources, nor any more widely familiar with the trends and tendencies in the conduct and support of hospitals in the United States than are Michael Davis and Rufus Rorem.

To those familiar with passing events as contributing public, the sick, and the doctor, hospital services, and what they cost, nothing of great novelty or originality appears in the twenty-one chapters of this book, but only particularly well informed and persistent

students of hospitalization problems will have been so fortunate as to have at hand and in logical sequence the excellent series of addresses and other documents here assembled on one theme.

The rapidly broadening reading public concerned seriously with correcting the errors of medical care and cost distributions, developed by the activities of the Committee on the Costs of Medical Care, will find much similarity between the facts and opinions here offered and the contents of many of the publications already issued by the committee.

After a description of the general situation which includes a summary of hospital facilities, capital investment, percentage bed use, and cost of maintenance of the hospitals of the United States, we are carried with generous but not elaborate tables and discussion through the economics of hospital care, the more pressing problems of hospital finance, of the depression era in particular, and finally to a somewhat philosophical consideration of the issues at stake and the experiments already under way toward solution.

Community Chest executives as well as hospital boards and county medical societies will find this book indispensable as a source of authentic information and sound policy, to say nothing of hospital superintendents, accountants, and public health councils and relief agencies.

HAVEN EMERSON

*Obstetric Education. Report of the Sub-committee on Obstetric Teaching and Education of the White House Conference on Child Health and Protection. New York: Century, 1932. 302 pp. Price, \$3.00.*

The Committee on Prenatal and Maternal Care of the White House Conference is to be congratulated upon this comprehensive study of obstetric education in the United States. The conviction

to plan efficiently for the most economical use of materials, and to make the small homes attractive in their mass as well as in proportions and detail. In these problems the designer needs the coöperation and help of the builders, contractors and the manufacturers of material and equipment.

HAVEN EMERSON

*Obstetric Education. Report of the Sub-committee on Obstetric Teaching and Education of the White House Conference on Child Health and Protection. New York: Century, 1932. 302 pp. Price, \$3.00.*

The Committee on Prenatal and Maternal Care of the White House Conference is to be congratulated upon this comprehensive study of obstetric education in the United States. The conviction

tion is growing that the main key to the prevention of maternal and early infant mortality rests in the hands of the well-trained obstetrician and midwife. This report considers every contingent phase of the subject and gives, in clear-cut recommendations, the steps which should be taken to improve obstetric education in this country. The parts on obstetric education of nurses and attendants, and on education of midwives should receive careful consideration. The education of the laity and social workers has been given special attention. The arrangement of the book is well fitted for reference purposes.

RICHARD A. BOLT

**Preventive Medicine**—By Mark F. Boyd, M.D. 4th ed. Philadelphia: Saunders, 1932. 532 pp. Price, \$4.50.

The fourth edition of this book, which is reset, proves that it has made a place for itself with teachers and those interested in public health. It has been brought up to date in almost all respects, though we fail to find any reference to psittacosis, which has become a public health problem in this country. The chief changes have been in the sections on milk supplies, water, and sewage disposal.

The book is well printed and abundantly illustrated, and will doubtless continue to hold the place it has won and occupied for 12 years.

MAZŮCK P. RAVENEL

**Sanitation Manual for Ice Cream Plants**—Prepared by the Research Committee of the International Assn. of Ice Cream Manufacturers, Harrisburg, Pa. *Special Bulletin No. 38*. 120 pp. Price, \$1.00.

Health departments have always placed particular stress upon regulation and sanitary control of milk and cream supplies. Milk products have received secondary consideration, and this has

been more or less true of ice cream. The results of this attitude have been exactly what would be expected, *i.e.*, that the milk industry has been educated to a high degree in the science of sanitation as applied to the food industry while the ice cream industry has not had the same advantages.

With an apparent realization of the situation the ice cream industry has, through the International Association of Ice Cream Manufacturers, done a laudable piece of work in the preparation and publication of two pamphlets designated as *Special Bulletin No. 21, Sanitary Regulations for Ice Cream*, and *Special Bulletin No. 38, Sanitation Manual for Ice Cream Plants*.

*Bulletin No. 21* was prepared in December, 1929, by the Committees on Sanitary Control of Ice Cream of the International Association of Dairy and Milk Inspectors and the International Association of Ice Cream Manufacturers. It was intended "for use of regulatory officials in the preparation of laws governing the manufacture and sale of ice cream and similar frozen foods, and as a guide to manufacturers in the operation of ice cream plants." The bulletin contains definite requirements in the form of a 10-section law and covers essential factors such as definitions; permits; premises; equipment; cleaning equipment; canning and packing ice cream; containers, packers, etc.; ingredients; pasteurization; and personnel; and also sanitary regulations for dealers and vendors of ice cream.

*Bulletin No. 38* was prepared by the Research Committee of the International Association of Ice Cream Manufacturers. The purpose of this *Sanitation Manual* is to assist ice cream plant operators to conduct their plant operations so as to comply with the terms of the sanitary code contained in *Bulletin No. 21*, and also to assist regulatory officials in their work. For the purpose of inspection record a "yes"

and "no" appraisal form is contained in the manual. The manual contains all of the provisions of the sanitary code and in many cases specific directions for carrying them out.

Food control officials interested in the sanitary control of ice cream supplies can gain much useful information from these bulletins and will find them essential in their work. Copies of the bulletins may be secured free by public health officials by communicating with Robert C. Hibben, Executive Secretary, International Association of Ice Cream Manufacturers, Harrisburg, Pa.

WILLIAM B. PALMER

**Emergency Work Relief**—By Joanna C. Colcord, Assisted by William C. Coplovitz and Russell H. Kurtz, Russell Sage Foundation, New York, 1932. 286 pp. Price, \$1.50.

This volume deals primarily with methods of administering work relief, and offers suggestions for those who are faced with the problem. Material for this study was collected from 26 American cities during the summer and early autumn of 1931 in response to a request from the President's Organization on Unemployment Relief. It was the aim to select projects in communities both large and small, conducted under a variety of auspices, public and private, and attended with varying success.

The book is divided into three parts, the last part perhaps containing the most constructive suggestions for community action. Part I deals with the development of work relief. Here are described legislative factors and methods of administration in the past. In at least 14 of the 26 programs described, the workers were protected by compensation insurance. In Grand Rapids, Milwaukee, and Niagara Falls, a medical examination was given before men were assigned to work.

Part II deals individually with reports on work relief in 26 communities.

From these reports, one is struck with the diversity of the inception, development, and conduct of work relief in the cities studied. Part III discusses the concepts underlying work relief and suggests methods of setting up a program. Several departments of municipal administration, as well as persons engaged in problems of relief and social service, will find much of interest in this timely volume.

IRA V. HISCOCK

**The School Health Program.** A publication of the White House Conference on Child Health and Protection. New York: Century, 1932. 400 pp. Price, \$2.75.

The report on *The School Health Program* is the most voluminous which has arisen from the White House Conference. It opens with a statement of the philosophy of education prepared by Professor William H. Kilpatrick. This is followed by a series of summarized reports of 24 sub-committees dealing with such subjects as the present school health activities; the school plant; mental hygiene; medical, dental, and nursing services; nutrition work in the schools; various phases of health education as applied to the elementary and secondary schools; social hygiene; physical education; etc. Special attention is given to problems of health in rural, negro, and Indian schools. A program of health for the parochial schools also is outlined. Due attention is given to the professional education of teachers and leaders in health education; and the importance of health service in teacher training institutions is stressed.

Under the able chairmanship of Dr. Thomas D. Wood, we have presented here a most comprehensive summary of the extent and diversity of school health problems. A composite review of many phases of the health and protection of school children is brought out by the

reports of various members of the subcommittees. This report forms a very useful background against which every progressive school system should check its actual accomplishments.

RICHARD A. BOLT

**The Modern American Family—**  
*Donald Young, Editor. Annals of the American Academy of Political and Social Science. Vol. 160. Philadelphia, 1932. 256 pp. Price, \$2.50.*

The student of the social and economic status of the family and its interrelations as the basic institution of modern society will find many valuable discussions collected in this volume. The papers edited by Donald Young, Ph.D., assistant professor of the Department of Sociology of the Uni-

versity of Pennsylvania, have been contributed by outstanding sociologists, psychologists, statisticians, specialists in welfare work, and clinicians.

The papers have been classified under three headings: The Heritage of the Modern Family, The American Family in Transition, and Efforts at Family Stabilization. Several of them touch upon the public health aspects of modern family life and the remedial agencies that have been established for improving the standard of American family life.

This book is especially valuable to the student of sociology and to welfare workers. It is well arranged, contains a helpful book department and index to subjects and names.

## BOOKS RECEIVED

**A CENTURY OF PUBLIC HEALTH IN BRITAIN, 1832-1929.** By Harley Williams. New York: Macmillan, 1932. 314 pp. Price, \$2.50.

**APPLIED BACTERIOLOGY.** By Thurman B. Rice. New York: Macmillan, 1932. 276 pp. Price, \$2.50.

**MY HEALTH HABITS. Book IV.** By Charlotte Townsend Whitcomb, John H. Beveridge and Evelyn Townsend McCrory. New York: Rand McNally, 1932. 249 pp. Price, \$.88.

**HEALTH STUDIES.** By F. M. Gregg and Hugh Grant Rowell. Yonkers: World Book Co., 1932. Home and Community. 258 pp. Price, \$.76. Personal Health. 314 pp. Price, \$.84.

**THE NEW HEALTHY LIVING SERIES.** By C.-E. A. Winslow and Mary L. Hahn. New York: Merrill, 1932. The Game of Healthy Living. 216 pp. Price, \$.64. The Habits of Healthy Living. 218 pp. Price, \$.64. The Laws of Healthy Living. 249 pp. Price, \$.64. The Healthy Community. 266 pp. Price, \$.68.

**OUTWITTING OUR NERVES.** 2d ed. By Josephine A. Jackson and Helen M. Salisbury.

New York: Century, 1932. 420 pp. Price, \$2.50.

**LIFE'S ADVENTURE. THE STORY OF A VARIED CAREER.** By Elwood Worcester. New York: Scribner, 1932. 362 pp. Price, \$3.00.

**CHILD CARE TODAY.** By Bela Schick and William Rosenson. New York: Greenberg, 1932. 320 pp. Price, \$2.50.

**ETHICS IN NURSING.** By Gene Harrison. St. Louis: Mosby, 1932. 163 pp. Price, \$1.50.

**CULTIVATING THE CHILD'S APPETITE.** 2d ed. By Charles Anderson Aldrich. New York: Macmillan, 1932. 137 pp. Price, \$1.25.

**ALCOHOL AND MAN.** Editor, Haven Emerson. New York: Macmillan, 1932. 451 pp. Price, \$3.50.

**YOUR HEARING. HOW TO PRESERVE AND AID IT.** By Wendell C. Phillips and Hugh Grant Rowell. New York: Appleton, 1932. 232 pp. Price, \$2.00.

**BACTERIOLOGY FOR NURSES.** 4th ed. By Mary Elizabeth Morse and Martin Frobisher. Philadelphia: Saunders, 1932. 409 pp. Price, \$2.50.

**THE MICROBIOLOGY OF FOODS.** By Fred Wilbur Tanner. Champaign: Twin City Printing Co., 1932. 768 pp. Price, \$7.50.

## A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

**Childhood Tuberculosis** — The author feels that the proper handling of tuberculosis in children requires a separate clinic adequately and competently staffed, and that the problem must be dealt with from the family angle. One more perfect example of beautiful printing which every health worker should take to heart.

BARNARD, M. W. A Tuberculosis Service for Children. Millbank Quart. Bull. 10, 4:257 (Oct.), 1932.

**Syphilis Control Through Treatment**—What it costs to treat syphilis in the hands of the general practitioner and at the pay clinic, and the relation of this cost to the ordinary patient's ability to pay, is set forth as an important factor in the spread of the disease because of the insufficient treatment many patients receive.

BROMBERG, L. and DAVIS, M. M. The Cost of Treating Syphilis. J. Soc. Hyg., 18, 7:365 (Oct.), 1932.

**Experimental Meningitis**—Meningococcus antitoxin injected after monkeys had developed critical symptoms following intraspinal inoculation with live meningococci protected the animals from acute cerebrospinal meningitis. Monkeys thus immunized were resistant to later lethal doses of organisms.

FERRY, N. S. Meningococcus Antitoxin. J. Immunol. 23, 4:325 (Oct.), 1932.

**Experimental Poliomyelitis**—Virus passed through monkeys intensifies its infectivity and undergoes quantitative changes. Virus-serum immunity is practical but the optimum protection is yet to be determined. Monkeys refractory to nasal infection are susceptible to intracerebral inoculation.

FLEXNER, S. Immunity to Human and Passage Poliomyelitis. J.A.M.A. 99, 15:1244 (Oct. 8), 1932.

**Nursing Motion Pictures**—Nursing technic, both for private duty and public health nurses, is the subject of a series of motion pictures used for nurse training. The idea might profitably be put to the training of inspectors and other health workers.

GOODRICH, A. M. The Nursing Procedure Motion Picture. Am. J. Nurs. 32, 10:1029 (Oct.), 1932.

**Colds and Diet**—Will ultra-violet light, irradiated ergosterol, cod liver oil, really increase immunity to colds as the enthusiasts would have us think? Not generally in infants, says this author. Neither are respiratory infections frequently due to a lack of vitamin A. But a lack of vitamin C may heighten local susceptibility in the respiratory tract. There's meat in this paper.

Hess, A. F. Diet, Nutrition, and Infection. New Eng. J. Med. 207, 15:638 (Oct. 13), 1932.

**High School Health Education**—Demonstrations of health education as conducted in some Massachusetts high schools are described briefly and possibly too modestly.

KIERNAN, F. Health Education Demonstrations in Massachusetts High Schools. New Eng. J. Med. 207, 14:604 (Oct. 6), 1932.

**Prenatal Clinic Results**—This report upon 218 complete clinic cases leads to some interesting conclusions. Too many made too few visits; the routine Wassermann proved its worth; and the value of physical examination was demonstrated. There was but 1 maternal death but the neonatal deaths were high.

NICOLL, M., JR. and MARSH, E. H. Report of Two Hundred and Eighteen Completed Cases Seen at the Westchester County Prenatal Clinic in 1931. New York State J. Med. 32, 20:1180 (Oct. 15), 1932.

**Possibilities of Mosquitoes Transmitting Tularemia**—"It is likely that suitable conditions to effect such transfers in nature are rare, and it is probable that at most only infrequent infection of man would occur in this manner." So concludes a demonstration of the possibility of the mechanical transmission of tularemia by mosquitoes.

PHILIP, C. B., *et al.* Experimental Transmission of Tularemia by Mosquitoes. Pub. Health Rep. 47, 43:2077 (Oct. 21), 1932.

**Rural Nursing**—Perhaps you are too hard headed to be influenced by perfect printing and appealing pictures. This story of public health nursing in Cattaraugus County seems so utterly convincing that this reviewer, for one, begins to suspect his own judgment. Perhaps he is only charmed by the printed page, so you had best read it yourself to form your own conclusion.

RANDALL, M. G. Public Health Nursing Service for Rural Children. Millbank Quart. Bull. 10, 4:276 (Oct.), 1932.

**Immunization Problems**—Limitations of artificial immunization and the desirable factors in the various procedures are set forth in stimulating generalities which introduced a British discussion of these subjects.

STALLYPASS, C. O. Problems of Immunization in Public Health. J. State Med. 40, 10:573 (Oct.), 1932.

**More Bacteriological Dissociation**—Dysentery type III bacilli develop

rough and smooth variants, the R type being the standard for cultures used in making antiserums. But it is the S type, not the R, that appears to be resistant to the serum. This is the cause of experimental errors, conclude the authors.

THIJOTA, T. and WAALLEP, E. Dissociation and Sensitiveness to Normal Serum in Dysentery Bacilli of Type III. J. Bact. 24, 4:301 (Oct.), 1932.

**Mental Reactions to the Depression**—The effect of adversity upon frank mental pathological states is measured statistically, whereas the more significant end-results can only be surmised.

THOM, D. A. Mental Hygiene and the Depression. Mental Hyg. 16, 4:564 (Oct.), 1932.

**Bacteriologic Tests of Water**—Only *B. coli* type colonies in a ferro-cyanide citrate agar medium are indicative of fecal pollution; *B. acrogenes* type and intermediate type colonies should not be considered dangerous; so concludes the author of this study.

TONNEY, F. O. and NOBLE, R. E. Colon-Acrogenes Types of Bacteria as Criteria of Fecal Pollution. J. Am. W. W. Assn. 24, 9:1267 (Sept.), 1932.

**Water-Borne Typhoid**—Causes of outbreaks of water-borne typhoid fever epidemics are set forth in interesting detail.

WOLPERT, N. N. B Typhosis is Waiting for You. Water Works Eng. 85, 19:1122 (Sept 21), 1932.

# NEWS FROM THE FIELD

## DELTA OMEGA HONORARY PUBLIC HEALTH SOCIETY

THE annual meeting of Delta Omega, the Honorary Public Health Society, was held in Washington, October 25, 1932, with the largest attendance in the history of the organization, including three honorary members, Colonel F. F. Russell of the Rockefeller Foundation, Dr. S. Josephine Baker, and Dr. M. P. Ravenel, editor of the *American Journal of Public Health*, and also General M. A. DeLaney, Acting Surgeon General of the U. S. Army.

Officers elected were: *President*, Dr. A. W. Freeman, Professor of Public Health Administration, Johns Hopkins University; *Vice-President*, Professor Ira V. Hiscock, Yale School of Medicine, and *Secretary-Treasurer*, Dr. W. G. Smillie, Professor of Public Health, Harvard University. Dr. James A. Tobey of the Massachusetts Institute of Technology Chapter was the retiring President.

Among other activities, the society, with the coöperation of the American Public Health Association, has republished Budd's classic work on typhoid fever, and this may be obtained by anyone interested, at a nominal cost, from the American Public Health Association, 450 Seventh Avenue, New York.

## DEATH OF DR. MONGER

DR. John Emerson Monger, F.A.P.H.A., died in Columbus, O., October 28. He knew more people in the public health profession than any other one man, and probably had more intimate personal friends than any other health officer. He was a most generous man with his time, his money, and his information. There have been many

stories of gameness in the arena, but never has there been a more perfect demonstration of sportsmanship than this man's life for the past four years. Beset with a chronic ailment which might terminate fatally at any moment, he never faltered in his attempt to improve the public health work of this country.

Dr. Monger was State Registrar of Vital Statistics for the State of Ohio 1916-1920, and Director of Health of Ohio 1923-1929. He was a member of the A.P.H.A. since 1923 and a Fellow since 1926. At the Washington Annual Meeting he was elected an Honorary Member of the Association. C. C. Y.

## NATIONAL REHABILITATION ASSOCIATION

THE National Rehabilitation Association, which is devoted to the promotion of vocational restoration of the disabled, determined at its convention in Chicago, October 10-12, to carry on an extensive campaign to place the need for the restoration of the handicapped before the people of the country.

The Association selected as Director John A. Lapp, of Chicago, formerly President of the National Conference of Social Work. Officers are: *President*, Oscar M. Sullivan; *Vice-President*, H. D. Hicker; *Secretary*, Homer W. Nichols; *Treasurer*, LeRoy N. Koonz.

## MICHIGAN WATER PURIFICATION CONFERENCE

THE Seventh Michigan Conference on Water Purification was held at Mt. Clemens October 5-7. The conference was unusual in that prepared papers were few and the members were given an opportunity for free discussion of plant problems at every session. This created an informal atmosphere

which caused many who would otherwise be inclined to refrain from comment to enter the discussion and was a condition commented upon by many who never attended before.

TEXAS ASSOCIATION CHANGES NAME

THE name of the Bexar County Public Health Association (San Antonio, Tex.) was changed by resolution of the Board of Directors at its regular meeting held in September to Bexar County Tuberculosis Association.

EXAMINATIONS OF CHILDREN

APPROXIMATELY 76,000 children entering school for the first time were examined under parent-teacher association direction in 1931. This number does not include many thousands of children of preschool age examined who did not enter school. It is anticipated by Summer Round-Up workers that the number of children examined this fall will exceed the number reported last year.

NEW YORK STATE SEWAGE WORKS ASSOCIATION

THE New York State Sewage Works Association held its Fall Meeting at Saranac Lake October 14-15, President Earle B. Phelps presiding. In the afternoon, after a brief business session, papers were presented by Henry W. Taylor; Ellis K. Phelps and Earle B. Phelps; and George Nesbit. The meeting unanimously adopted a resolution protesting against drastic or unproportionate reduction in maintenance funds for municipal sewage treatment works. The Fifth Annual Meeting of the Association will be held in New York City in the middle of January, 1933.

CAN WE REDUCE ACCIDENTAL DEATHS?

LAST year accidents of all kinds caused 4,634 deaths in the City of New York, 1,298 of these being charged

to automobiles. . . . It may be well to bear in mind that other accidents also deserve attention. Arranged in the order of frequency, and omitting accidental deaths due to machinery or to means of transportation, these other accidental deaths in New York City in 1931 were charged to the following causes:

Accidental falls and crushing.....	1,356
Drowning . . . . .	435
Illuminating gas . . . . .	305
Accidental burns.....	232
Acute poisoning.....	108
Gases other than illuminating....	70
Sunstroke . . . . .	66
Injuries from cutting or piercing instruments . . . . .	64
Conflagration . . . . .	59
Mechanical suffocation.....	31

Of the 435 deaths from drowning 409 were in males. With the great popularity of bathing among both sexes it is probable that the number of lives exposed was not much if any greater among males than among females. The former, however, are more reckless and pay the penalty. An examination of the drowning deaths by age fails to show much greater frequency of this accident at any particular age period. In other words, so far as this accident is concerned the male does not appear to acquire greater caution as he grows older. In fact the rate from drowning appears to be highest among males in the age period 35 to 50. It is not a tribute to man's common sense.

When we examine deaths from accidental burns we find they are more numerous among females, 102 males to 130 females. Moreover, a large proportion of these deaths occur in children under 5, namely, 25 males and 47 females. During the next 5 years they are also quite numerous, 11 males and 16 females, but after that they drop quickly to a low point between 15 and 25 years.

Except for accidental deaths due to automobile and street accidents and to accidents caused by machinery, there is little in the way of administrative measures that can be done to reduce these unnecessary deaths. Almost entirely is it a question of educating and training the individual. Perhaps our school teacher readers can utilize the material here presented to teach the lesson.—*Weekly Bull.*, City of New York, 22:35 (Sept. 3), 1932.

#### DEMAND FOR VACCINES INCREASE

THE demand for vaccines and other preventive material has increased enormously during the last three years in Illinois and the trend is still upward. Since January, 1929, fully one-half million children have been immunized against diphtheria with toxoid and toxin-antitoxin furnished by the State Department of Public Health compared with 300,000 during the previous four years. Over a quarter of a million people were vaccinated against smallpox with vaccine distributed by the department, compared with less than 75,000 during the preceding quadrennial. The number of people vaccinated against typhoid fever with material furnished by the department jumped from 60,000 to 75,000 in the two periods, respectively. To determine the susceptibility of children to diphtheria the department distributed material sufficient for 135,000 and 65,000 tests during the two periods, respectively. The results of this growing demand for preventive medicine are reflected in lower prevalence rates of the diseases subject to control by these methods.—*Illinois Health Messenger*, Nov. 15, 1932.

#### NORTH CAROLINA WATER WORKS ASSOCIATION

THE North Carolina Section of the American Water Works Association and the North Carolina Sewage Works Association held its Twelfth

Annual Joint Convention at Winston-Salem October 31, November 1-2.

#### RESIDENTIAL SANITATION

D R. R. H. Riley, Director of the Maryland State Department of Health, announces that the department has issued a pamphlet on residential sanitation, containing practical suggestions for solving the more important sanitary problems that affect the welfare of those living in rural homes.

A copy may be obtained by writing to the Bureau of Sanitary Engineering, Maryland State Department of Health, 2411 North Charles Street, Baltimore.

#### PRESERVATION OF FOOD BY DRIKOLD

IN England the government maintains a station at Cambridge where researches on low temperatures for the preservation of foods are carried out, and another station at Aberdeen, devoted to the preservation of fish. The use of solid carbon dioxide known in England as "drikold" and in this country as dry ice, has already revolutionized the methods for preservation heretofore in vogue. Dry ice is extensively used in the ice cream industry, and in the transportation of fish and other perishable foodstuffs. The researches in England have proved that meat and fish can be kept for long periods in perfect condition when stored in chambers the atmosphere of which has been displaced by carbon dioxide and which are maintained at definite low temperatures. The action of the cool carbon dioxide gas inhibits bacterial deterioration, and the meats do not suffer the deterioration caused by ordinary chilling or refrigeration. The report points out that at present meats from Argentina, Australia, and New Zealand have to be frozen to arrive in edible condition in England, but by the new process, this will not be necessary. Applied to fish, the process seems to hold even more important potentialities.

The great bulk of fish eaten in England is brought from as far north as Greenland and Murmansk, the southern waters not having been fished for this purpose on account of the impossibility of transporting the catch to England in edible condition. So far, practical methods of applying the discovery to trawlers, storage houses, railway cars, etc., have not been worked out in detail, but there seem to be no insurmountable difficulties in doing this.—*Med. Off.*, Sept. 10, 1932, p. 113.

#### CHILD HEALTH CENTER, ALBANIA

THE establishment of a child health center in Albania was the first step in a campaign against infant mortality. Because the methods of child care in the villages and even in the cities are very unsatisfactory the committee conducting the campaign decided to organize courses for mothers; these courses are well attended. In the capital, Tirana, courses for the training of midwives were organized, and some women were sent to France for post-graduate study.—*Maternità ed Infanzia*, Rome, Sept., 1932.

#### NEW PASTEURIZING PROCESS ILLEGAL IN ILLINOIS

A NEW development in pasteurizing equipment which is a modification of the old "flash" method has been the subject of research and study by various persons and organizations during the past few years.

This new method is known as "short time" pasteurization and consists of heating milk to a temperature of 162° F., and holding at that temperature for a period of 15 seconds.

The milk committee of the A.P.H.A. reported at the Montreal convention on studies and experiments with new type short time pasteurizers. The conclusion that may be drawn from this report is that "short time" pasteurization will produce safe milk from a public health

standpoint. Commercially it is said to have many advantages over the holding method now in use.

Some Illinois pasteurization plant owners are showing interest in the "short time" pasteurization method. However, Illinois law requires that milk or milk products be heated to a temperature of not less than 142° F., and held at such temperature for not less than 30 minutes. To permit the use of "short time" pasteurization in Illinois, it will be necessary to amend the existing law.

The New York State Department of Health and Pennsylvania Board of Health have approved "short time" pasteurization. Texas State Department of Health has indicated that "short time" pasteurization will be permitted in that state.—*Illinois Health Messenger*, Nov. 15, 1932.

#### PERSONALS

C. O. SAPPINGTON, M.D., DR.P.H., F.A.P.H.A., of Chicago, is now conducting a new service as consultant on problems of Medicine and Hygiene in Industry.

JOHN A. LAPP was elected Director of the National Rehabilitation Association at their convention in Chicago October 12.

DR. WILLIAM WALTER CORT, professor of helminthology and head of the department, School of Hygiene and Public Health, Johns Hopkins University, delivered the annual address of the Alpha Alpha chapter of Alpha Epsilon Delta, University of Alabama, on November 16, 1932. His subject was "The Hookworm Problem in the United States." Following the lecture, honorary membership in Alpha Epsilon Delta was conferred upon Dr. Cort.

#### DEATH

MORRIS KNOWLES, F.A.P.H.A., Sanitary Engineer of Morris Knowles, Inc., Pittsburgh, Pa., died November 8.

## FOOD AND NUTRITION

The Vitamin A, B, C and G Content of Sultanina (Thompson Seedless) and Malaga Grapes and Two Brands of Commercial Grape Juice—Although the literature has reported raisins as containing little vitamin A, and small amounts of B and C, there is little published on the vitamin content of fresh grapes and grape juice. Thompson Seedless and Malaga grapes were the varieties studied and two types of commercial grape juice, (1) a mixture of Flame Tokay and Zinfandel, and (2) juice from Concord grapes. In both cases, the juice is pasteurized before putting on the market.

In the studies on grapes the basal diet was irradiated to supply vitamin D, and after depletion supplements of Malaga and Sultanina grapes were fed the rats. A small amount of vitamin A was indicated in the two varieties of grapes, but neither of the juices tested showed any indication of this vitamin. The animals died before completion of the experiments, and upon autopsy showed vitamin A deficiency.

The vitamin B (antineuritic) was tested on rats on a diet complete except for the antineuritic vitamin. After a 2-week period the supplements of grapes and grape juice were fed. Five and 6 gm. of the grapes produced the maximum effect of vitamin B, an average gain in weight of 17.5 gm. in the case of Malaga, and in the case of Sultanina an average of 18.8 gm. on 5 gm. of grapes, and 21.6 gm. on 6 gm. portions, showing the grapes are a fair source of the antineuritic vitamin. No measurable quantity of this vitamin could be found in the commercial juices studied.

The vitamin C tests on commercial

juice No. 1 were carried out according to the Sherman technic. The tests on the grapes and on the Concord grape juice were made according to the Höjer method. During the 18-day test periods, 10 and 12 c.c. portions of grape juice were fed to guinea pigs and the grapes in 2, 5, 10, and 15 gm. portions.

All of the teeth of the guinea pigs receiving Concord grape juice showed pathological conditions similar to the controls, indicating no appreciable amount of vitamin C. Two and 5 gm. portions of both varieties of grapes did not prevent the pathological changes in the teeth. Ten gm. of grapes showed slight protection but even 15 gm. was insufficient for borderline protection.

In the case of vitamin G, tests on young rats indicated a small amount of this vitamin in the Sultanina but the Malaga grapes and both commercial grape juices did not show evidence of this vitamin.—Esther Peterson Daniel and Hazel E. Munsell, *J. Agri. Res.*, 44: 59 (Jan. 1), 1932.

**The Amino Acid Deficiencies of Beef, Wheat, Corn, Oats, and Soy Beans for Growth in the White Rat**—Paired rats were used in the study of the amino acid deficiency of these foodstuffs and to determine which combinations of foods would be nutritionally advantageous. Rats were weighed weekly and at the termination of the experiment, lasting from 5 to 12 weeks, body lengths were determined, so as to compare differences in pair mates in body lengths and body weight.

Lean beef at the 8 per cent protein level showed an average of 1.89 gm. daily gain for controls and 2.09 gm. for those with the cystine supplement.

When fed at the 20 per cent protein level, greater daily gains averaging 2.78 gm. were noted, but added cystine resulted in no appreciable effect on growth.

Wheat at the 8 per cent protein level showed no increased growth with the cystine supplement but when lysine was substituted for the cystine the lysine-fed rats gained faster than the controls. With oats at the 8 per cent protein level, the lysine supplement showed 1.38 gm. daily gain against 1.30 for the controls. In the case of soy beans, cystine supplement showed greater gains than the controls and greater body lengths. Corn at the 8 per cent protein level was supplemented with lysine and then with tryptophane, the former showing a small effect. Tryptophane showed no supplementing effect at this protein level. Tryptophane added to a corn ration at the 8 per cent protein level, already supplemented with 0.25 per cent of lysine, resulted in distinct gains in weight and body lengths. Tryptophane added to corn unsupplemented with lysine showed a slight depletion in gain in weight but no effect on body lengths.—H. H. Mitchell and D. B. Smuts, *J. Biol. Chem.*, 95: 263 (Feb.), 1932.

**The Relation Between Dietary Cystine and the Growth and Cystine Content of Hair in the Rat**—Paired feeding experiments were the basis of the work reported to determine the relation between cystine and hair growth. At the conclusion of the experiment, the rats were killed and hair completely removed from the body, thoroughly dried and weighed. The hair growth measurement was determined by computing the weight of dried hair per sq. cm. of body surface.

The rats were fed the same rations as were recorded in the experiment of Mitchell and Smuts on amino acids. With beef at the 8 per cent protein level previously supplemented by cystine all pairs exceeded the controls in weight of

hair per sq. cm. of body surface as well as in the cystine content of the hair itself. On the 20 per cent protein level, the cystine supplement did not show increased hair growth, but a reduction in most instances.

In the case of the wheat protein, very little difference was noted in the hair growth and hair per sq. cm. in the rats on the supplemented diet. When cystine is added to a diet which is not deficient in this amino acid it exerts no special effect on hair growth and cystine content or keratinization of the hair.—D. B. Smuts, H. H. Mitchell and T. S. Hamilton, *J. Biol. Chem.*, 95: 283 (Feb.), 1932.

**The Necessity of Copper as a Supplement to Iron for Hemoglobin Formation in the Pig**—The authors having announced in an earlier paper (*J. Nutrition*, 2, 277, 1929–1930) that ferric chloride effected almost as rapid recovery in anemic pigs as iron and copper together, this experiment was undertaken with particular care to eliminate all possible contamination by copper.

Suckling pigs were taken from their mothers at 5 days of age and put into individual wooden pens and given whole cow's milk until they were distinctly anemic. Iron as purified ferric chloride was then given and when no further improvement was shown copper as copper sulphate was added. Hemoglobin was determined weekly. All pigs developed anemia within 4 weeks on the milk diet, and were kept anemic until the hemoglobin decreased to values below 2 gm. per 100 c.c. of blood.

Twenty-five mg. of purified  $\text{FeCl}_3$  raised the hemoglobin content 5 gm. in 4 weeks. When no further improvement was noted, 5 mg. of copper in addition to the iron effected a rapid improvement in all pigs, hemoglobin values being raised from 3.6 to 12 gm. per 100 c.c. of blood in 5 to 6 weeks at-

tended with increased activity of the pigs.

From this experiment the authors conclude that where experiments report hemoglobin regeneration due to iron alone, there is a probability that the animals are receiving sufficient copper from some other source.—C. A. Elvehjem and E. B. Hart, *J. Biol. Chem.* 95: 363 (Feb.), 1932.

**The Effect of Pasteurization on the Bacterial Flora of Low Count Milk**—Improved methods of milk production during the past few years have resulted in a marked reduction of the bacterial contamination of raw milk. As a result of the pasteurization of this low count milk certain problems have been developed which were not often encountered when milk of a greater bacterial content was being passed through the pasteurizer. It was noted (1) that such milk frequently does not coagulate even after a considerable period of time, and (2) that the absence of coagulation is oftentimes accompanied by the development of pronounced off flavors and odors.

Studies carried out at the State College of Washington were designed to give information on the types of bacteria surviving the pasteurization of low count milk, the changes occurring in the developing flora subsequent to pasteurization and the relation of this flora to the changes taking place in the milk.

Twenty samples of freshly drawn morning's milk were used in this experiment. Each sample was divided into two equal portions and one portion pasteurized at 142° F. to 143° F. for 30 minutes. Both the raw and the pasteurized portion of each sample were divided again, and a representative sample of each incubated at temperatures of 68° F. and 45° F. respectively.

Each sample under observation was examined for flavor daily, and when an off flavor had developed so that the

milk was unfit for consumption it was considered spoiled. Differential and total bacterial counts were made on the raw and pasteurized portions of each sample at the time they were fresh, and again at the time when spoilage was evident. These counts were determined on Bacto-nutrient-caseinate-brom-cresol-purple agar plates, incubated at 37° C. for 48 hours. Acidity and Cooledge score determinations were made on the raw and pasteurized portions of each sample at the time the samples were fresh and at the end of each 24 hours throughout the incubation period. The average bacterial count on twenty samples of fresh milk before pasteurization was 3,467 per c.c., and after pasteurization 377 per c.c.

The bacterial flora of raw and pasteurized milk was divided into three principal groups: (1) Acid-producing types, (2) Proteolytic types, and (3) Alkali forming and inert types.

The differential plate counts showed the comparative percentages of these bacterial groups developing in incubated raw and pasteurized milk.

*Percentage Distribution (based on average for 20 samples)*

<i>Initial Raw Milk</i>	<i>Initial Pasteurized Milk</i>
Group 1 = 26.17%	14.64%
Group 2 = 0.76%	0.62%
Group 3 = 73.07%	84.74%
<i>Raw milk incubated at 68° F.</i>	<i>Pasteurized milk incubated at 68° F.</i>
Group 1 = 68.69%	25.51%
Group 2 = 0.038%	23.74%
Group 3 = 31.25%	53.76%
<i>Raw milk incubated at 45° F.</i>	<i>Pasteurized milk incubated at 45° F.</i>
Group 1 = 62.15%	11.38%
Group 2 = 11.29%	13.85%
Group 3 = 25.56%	74.77%

The Cooledge score and titratable acidity determinations furnished additional correlative evidence relative to the groups of organisms responsible for the changes occurring in incubated raw and pasteurized milk.

The results of this investigation indicate that when milk of low initial bacterial content is pasteurized, the acid-

producing bacteria are not of major importance in the spoilage of the milk. The results of this examination also indicate that spoilage in this type of pasteurized milk as determined by off flavor and odor without souring may be attributed to the action of the proteolytic and alkali-forming and inert types of bacteria.

The evidence reported in this paper bearing on the groups of bacteria surviving pasteurization and causing the subsequent changes in milk does not fully agree with the results obtained by other investigators. The authors suggest that this disagreement in results may be due to the fact that other investigators have worked with milk of a relatively high initial bacterial content, while this work was carried out with milk of a relatively low initial bacterial content.—L. A. Black, C. C. Prouty, and R. A. Graham, *J. Dairy Sci.*, 15: 99 (Mar.), 1932.

**Vitamin B Content of Bread—**Previous investigations having indicated the probability that vitamin B in bread is largely dependent upon the amount of yeast, work was undertaken to determine how much brewer's yeast should be added to bread to provide for a sufficiency of this vitamin.

Commercially baked bread containing variations in the quantities of dried brewer's yeast was fed to pigeons. The supplements of dried yeast varied from 0.36 per cent to 1.2 per cent. The pigeons were fed only the bread and

water. When no supplement of brewer's yeast was added, the pigeons suffered from polyneuritis. Pigeons which lost weight on yeast-free bread recovered with the bread containing 0.3 per cent dried brewer's yeast, although slower than those which received a supplement of 0.5 per cent.

In one group, pigeons which were fed at the start with 1 per cent yeast supplement, which was then substituted with bread containing 0.3 per cent, showed evidence of malnutrition and one bird had polyneuritis. In other pigeons a decrease from 1 to 0.5 per cent, then 0.3 per cent, showed only slight evidence of vitamin B deficiency.

Another experiment was undertaken to determine the effect of heat and pH on vitamin B activity. The pH of the dough was 5.6 and the finished loaf 5.5, and the temperature in the center of the loaf was 90 to 100° C., during baking, for only a few minutes. Similar results were obtained by feeding this bread with its supplement of dried brewer's yeast as were reported by other investigators who fed the yeast independent of the bread.

From these experiments it was concluded that bread is deficient in vitamin B but this may be supplemented by the addition of brewer's yeast in amounts sufficient for pigeons between 0.3 and 0.4 per cent, and that the pH and temperature in baking do not destroy the vitamin B activity.—Yoshitaka Hashitani and Tsunenaka Sako, *Cereal Chem.*, 9: 107 (Mar.), 1932.

## INDUSTRIAL HYGIENE

**New Safety Code for Elevators—** A revised safety code for elevators has been completed by the U. S. Bureau of Standards and has been approved by the American Standards Association. The code embodies new types of control and additional safety provisions made necessary by the advent of high speed elevators. Elevator buffers have been redesigned and specifications for tests on buffers, terminal stops, interlocks, and safeties have been developed.

The code permits two story elevators to serve two stories at the same time, two operators being used. Provisions are made so that the elevators may not be put into motion unless both doors are closed. The safe operation of freight and passenger operated elevators as well as dumb-waiters and escalators are covered by this code. *Month. Labor Rev.*, 34, 3: 569 (Mar.), 1932. L. G.

**Coal Mine Accidents in United States—**Recent statistics reported by the U. S. Bureau of Mines for the year 1929 disclose a fatality rate of 3.19 per million tons mined in bituminous mines, a decrease from the year 1928. For anthracite mines the rate was 6.53 an increase over that for 1928. There were 2,187 deaths in coal mines in 1929 yielding a rate of 3.59 per million tons, a decrease from a rate of 3.78 deaths per million in 1928. *Monthly Labor Review*, 34, 3: 569 (Mar.), 1932.

L. G.

**The Impinger Dust Sampling Apparatus as Used by U. S. Public Health Service—**This contribution describes the present form of the Greenburg-Smith impinger apparatus as used by the U. S. Public Health Service. The essential portion of the apparatus is the

impinger tube and sampling flask or bottle through which air is drawn by means of an electrically driven, compressed air driven, or hand actuated suction device. The method of sampling and analysis of the dust is described in detail. The impinger apparatus has found wide use in the sampling of air, not alone for atmospheric dust but also for chromic acid mist, lead dust and fumes and sulphur dioxide.—Leonard Greenburg and J. J. Bloomfield. *Pub. Health Rep.*, 47, 12 (Mar. 18), 1932.

L. G.

**The Measurement of Radiant Heat in Relation to Human Comfort—**This interesting and valuable contribution serves to emphasize the importance of radiant heat in the estimation of indoor atmospheric conditions along with dry bulb temperatures, relative humidity and air motion.

In order to determine the radiation heating effect the author experimented with several different types of black body thermometers. The most satisfactory was found to consist of a mercury and glass thermometer inserted into a globe made of thin sheet copper, 6 inches in diameter. The outside of the globe was painted mat black.

Studies made with the copper globe thermometer using a gas fire, stove, and ceiling panels as the source of heat, indicated the subjects to be comfortable at temperatures ranging from 61.4 to 62.9°; these temperatures being the total of the air temperature plus the corrected effectual radiation temperatures. The mean surface temperature of the clothing of the two subjects used in these experiments ranged from 70.8 to 73.6°, taken at 7 points on the body.

Observations made with the copper

globe thermometer with heating sources of various kinds, either stoves, overhead heaters, ceiling panels and underfloor heaters, indicated that, as might be expected, the globe thermometer is to some extent selectively warmed, depending upon the location of the heating source with respect to the thermometer. It is to be noted that with a ceiling panel 9 feet above the globe thermometer the top segment of the thermometer possesses an excess temperature of  $2.6^{\circ}$  and the bottom segment an excess temperature of but  $0.8^{\circ}$ . With ceiling panels at a temperature of about  $95^{\circ}$  radiation is so mild as to be scarcely perceptible to the head of a person sitting directly beneath.

Experiments made in a large lecture hall equipped with a ceiling hot water panel heater and an auxiliary plenum air system showed that negative radiation (cooling) was produced by the cold walls and floor of the room, in spite of the fact that the plenum system was delivering air at a relatively high temperature.

In these experiments it was found that a far more uniform and equable temperature was maintained by the panel heating system when the plenum system was discontinued. The author concludes that "an air current of 270 feet per minute lowered the effectual radiation temperature induced by a gas fire to less than a half, and lowered that induced by a stove to a third of the respective radiation temperatures observed in still air."—H. M. Vernon, M.D., *J. Indust. Hyg.*, Mar., 1932, pp. 95–111. L. G.

**Recent Research into the Causes of Industrial Accidents**—Although the avoidance of dangerous practices and the guarding of machinery have ac-

complished considerable good in the prevention of accidents, there is still room for additional measures designed to reduce the frequency of industrial accidents. The author points out that, of the external factors affecting accident causation, fatigue, and poor atmospheric and lighting conditions may be important contributory factors. Accidents appear to be more numerous among younger persons, and among those who experience higher accident rates, the rate of illness is as a rule high.

The personal factors affecting accident causation are discussed by the author, who points out that certain persons are more prone to accidents than are others, and that those having an excess number of trivial accidents, as a rule suffer an excess number of more serious accidents. As a result of recent investigations of accident statistics, it has been possible to construct a very valuable table "by means of which it is possible to determine whether the accident rate of a department is mainly due to factors affecting all members equally or to the fact that it contains certain accident prone individuals." The value of such a procedure is obvious, and it seems equally obvious that great benefit should, at least in certain cases, result from studies of this type.

Psychologic studies showed that persons who failed in certain sensorimotor tests had an accident rate two and one-half times greater than those who had passed these tests.

The importance of complete accident and sickness records is stressed as an aid in the prevention of accidents. In this connection the use of the card index system is preferable in the opinion of the author.—Eric Farmer, *J. Indust. Hyg.*, 14, 3: 84 (Mar.), 1932. L.G.

## CHILD HYGIENE

THE day peculiarly the child's own is May Day. During the past 8 years the interest and attention of the nation have been gradually drawn to a specific consideration of children's health needs upon that day. One city that was particularly interested in May Day in 1931 was Springfield, Mo., and it developed this interest in a "May Day Conference" during a period of 3 days. The Parent-Teacher Association sponsored the program.

Committees were planned after the manner of the White House Conference Committees, but the studies made were confined to the city of Springfield. Committee A was called "Healthful Living Through the Twenty-four Hour Day," and was composed of 5 sub-committees. One of these sub-committees was on the "Home's Contribution to Health Education," and had a parent for chairman. The other 3 members were a school nurse, a classroom teacher, and a principal. The chairman sent a letter to 61 principals and teachers, representing 21 schools, asking each teacher to call a meeting of parents of the children in her room for the purpose of getting facts regarding home health habits of their children. Three hundred and ninety-seven mothers attended and 1,313 children were represented.

The mothers were asked to list facts about the health habits of their children while at home, and the following tabulated results came from these meetings:

Health habits being practiced in the home	129
Health habits which, in the parents' opinions, are difficult to establish	101
Health habits with which the mothers wish aid	71

From this material the committee reached 4 definite conclusions, and made the recommendation that "Some form of health edu-

cation be established whereby parents may get a better knowledge of how to direct their children in desirable health habits—mental, emotional, social, and physical." The committee goes on to give a detailed plan of how this may be done in Springfield, Mo. This is an excellent program because it is an outgrowth of their own study, stimulated from without by a national organization and by the White House Conference, but adapted to their own needs.

Portland, Ore., observed May Day in a variety of ways. One of the most far reaching of these was a series of 18 radio talks on the points of the Children's Charter, sponsored by the Portland branch of the American Association of University Women, and broadcast over KGW. Each talk was definitely tied up with the White House Conference.

County nurses, May Day chairmen, and others organized groups of mothers and clubwomen all over the state to listen to these broadcasts, scheduled from March 21–April 30. At club dinners and Health Association dinners and at school exercises the White House Conference was also the principal topic of the speakers.

Newspaper advertisements in the leading Portland papers contained frequent references to May Day—Child Health Day. The official *Bulletin* of the Portland churches with its series of May Day articles also reached many people. Newspapers, stores and other business firms, as well as men's and women's clubs, took an active part in spreading the May Day message of child health.

The School Division of the City Health Bureau coöperated with the Parent-Teacher Association in a huge Summer Round-up of the children. At 45 clinics 1,026 children were examined—an increase of 319 over last year. In almost every instance the mothers accompanied the children to the clinic and received advice and recommendations from the physician.

Visiting nurses, doctors at the infant welfare conferences and visiting teachers sponsored special projects and talks on child health. A new step was taken by the Visit-

ing Nurse Association in its May Day talks to student nurses at 2 of the hospitals. At 2 of the libraries meetings were held for prospective mothers, and the Portland Library Association displayed announcements and posters on May Day, and recommended children's books and books on child care. At the Marshall Street Community Center where the regular monthly meetings for mothers had their origin in an earlier May Day, there were programs for both mothers and children. The Neighborhood House also gave its annual May Festival.

The Portland League for the Hard of Hearing held a meeting on May 2 reporting on what the organization is doing for the handicapped child. Through the Girl Scouts, Camp Fire Girls, 4-H Clubs, Young Men's Christian Association and Young Women's Christian Association many hundreds of young people and their parents observed May Day in health contests and Play Day events.

Close on the heels of May Day, comes Mother's Day, which the Maternity Center Association of New York City would turn into something better than an occasion for greater commercial activity throughout the country. It suggests that the practical demonstration of affection for the mothers of the country would be to assure them safety in becoming mothers and strength and health afterward. Its efforts have not extended over so long a period as those for the observance of Child Health Day, having been started only in 1930, but they are equally deserving of attention.

The association calls attention to the fact that the puerperal death rate in the United States is unnecessarily high, that it can be reduced greatly by adequate and skilled obstetric care, and that the

public should be educated in the essentials of such care. It has sent out material to daily and weekly newspapers, magazines and trade journals all over the country; the Metropolitan Life Insurance Company, the Borden Company, and Parke-Davis Company devoted newspaper and magazine display advertising to the importance of adequate maternity care; governors and mayors issued proclamations and health commissioners wrote articles and broadcast over the radio; ministers preached sermons regarding better maternity care.

This year the Medical Society of the State of New York is taking the lead in that state to teach the public the need for adequate maternity care. This society approved a plan to send every physician in the state copies of a leaflet for distribution to patients, entitled "A Message to Expectant Mothers and Fathers from the New York State Medical Society." This circular outlines the fundamentals of maternity hygiene advising medical care from the time the woman believes she is pregnant until the doctor says she is able to resume her regular activities and responsibilities and to care for her baby.

These leaflets are not being sent to physicians directly by the society, but through the coöperation of the Maternity Center Association of New York City. A letter accompanies the circulars offering to send physicians additional quantities if desired, and the response from the medical profession is very favorable.

## PUBLIC HEALTH NURSING\*

**County Public Health Nursing in Texas**—The area of Texas is approximately the same as the combined areas of Wisconsin, Michigan, Illinois, Indiana, Ohio, and Kentucky. Few realize the vastness of the state whose climate ranges from the semi-tropical in the south to ice and snow and frosty winter winds in the north. In the west are the prairies and plains where cities and industries are fast developing, in the east is the pine country with its cotton fields and large negro population.

Texas has 254 counties within its borders. Forty of these have full-time county nursing services. There are 200 counties left which have no organized public health nursing service.

It was the Texas Congress of Parents and Teachers which years ago petitioned the legislature for a Bureau of Child Hygiene in the State Department of Health, and it was successful. As in many other states, the American Red Cross helped this department get started by financing and supervising county nursing services jointly with the state. During the first year of the bureau, the University of Texas had a School of Public Health Nursing and trained 58 public health nurses who were placed in counties throughout the state. From 1921 to 1929 federal money which came to Texas through the Shepherd Towner Act helped greatly to expand local public health nursing services. Since then the State of Texas itself has financed the nursing program. The bureau's plan now is to put as much money as possible directly into nursing services in the various counties, and in order to

stretch the appropriation over as large a territory as possible, the counties are asked to match the state and federal funds for this work. Since May, 1931, also, 22 public health nurses have been serving in 100 counties in the drought area of Texas on emergency funds from the federal government.

The state does not inaugurate public health nursing services in a county unless there is a nursing committee formed to be "additional arms, legs, and brains to help with community health problems." This committee promotes the work of the county nurse and interprets the public health nursing program to the people. It is made up of representative people such as the county health commissioner, the county superintendent of schools, the chairman of the county council of parents and teachers, and others. A field supervisor of nursing is provided by the state bureau to assist in organizing county committees and nursing organizations and to give every help possible to the nurse when she is employed.

In order to show the great number of counties in Texas which had never had public health nursing services what they could accomplish, 2 years ago a special appropriation was made by the legislature to the Bureau of Child Hygiene, which provided for 4 white and 2 negro state itinerant public health nurses. The state finances these itinerant services entirely and the nurses stay from 4 to 6 weeks in a county. In order to have these nurses the counties must meet certain definite requirements: (1) a written request for the service must go to the State Department of Health from certain officials and representatives of certain service clubs; (2) an endorsement and request must come

\* For a recent printed matter on other material relating to public health nursing to E. J. MacDonnell, State Health Officer, Indianapolis, Ind.

from the county medical society; (3) a county health committee must be appointed by the county court to assist the nurse; (4) the county must furnish incidentals needed in the nurse's work, and an office.

The negro itinerant nurses work entirely with their own race, and they have received wonderful coöperation.

The American Red Cross has also furnished itinerant nursing services in Texas for several years. The Red Cross itinerant nurse remains from 3 to 6 months at a time in a community. Her salary and other expenses are paid by the American Red Cross, and the Chapters receiving the service reimburse the national office.

As a result of the itinerant nursing services, several counties have employed full-time nurses. Many of the other counties which have had a taste of this service are determined to continue to work for an appropriation to finance a full-time nurse. Counties are sending in more requests for itinerant nurses than the state can grant. The itinerant nurses have "provided an opportunity for the general dissemination of individual education in public health, the value of which cannot be measured by statistics or during a single generation" in counties that have previously showed no concern about public health matters.

**The Public Health Nurse and Rural Sanitation**—Recently the Sanitary Engineering and the Public Health Nursing Departments of the Indiana State Board of Health held a Sanitary Institute for public health nurses in southern Indiana. The nursing department in preparing its part of the pro-

gram searched through a great many books and public health and nursing magazines for material on this subject as it applied specifically to public health nurses. Almost nothing was found.

On a recent visit to the Tennessee State Health Department at Nashville the matter was discussed with Malvinia Nisbet, Supervisor of Public Health Nurses, and she mentioned a paper which H. S. Mustard, M.D., of the Tennessee State Department of Health had read at a Regional Health Workers' Conference held in Tennessee in 1931. Dr. Mustard gave the following as duties and opportunities of the public health nurse in a county health department in the execution of an environmental sanitation program:

1. To gain a clear understanding of the scientific basis of sanitation as it relates to prevention of specific diseases.
2. To gain a clear understanding of the sanitary problems of the area as a whole, of every community, and of each home visited.
3. To gain a clear understanding of the sanitation program in all its phases, both as to policies and procedures, and also as to technic.
4. To integrate each visit directly or indirectly with the need for sanitation. In one way or another this is possible with every service rendered by the public health nurse.
5. To exert a special effort, in cases where communicable diseases exist, to insure immediate provision of sanitary improvements: protected water, milk control, proper excreta disposal, insect exclusion, or even the wearing of shoes in hookworm families.
6. To assist intelligently, interestedly, and tenaciously in discovering the source contacts in those diseases whose spread is associated with defective environment. This applies particularly to painstaking investigation in connection with typhoid fever. Often a nurse, through the woman of the house, can gather information and can obtain stool and urine specimens, where others would be unable to obtain this material for laboratory examination.
7. To teach in the home the essentials of milk and food sanitation. Such instruction may vary from protection of food from flies to removal of the privy from the vegetable garden.
8. To teach in the home the use and care

of screens and to demonstrate the patching of screen wire.

9. To teach the importance of safe excreta disposal and safe water, and to explain how these improvements may be brought about.

10. To make a sanitary survey of every home visited, go over the existing situation with the woman of the house, to make to her recommendations for improvement, recording findings on Form No. 300, and routing this record to the files through the sanitary inspector.

#### REFERENCE

Papers presented at Regional Health Workers' Conference, Tennessee Dept. of Public Health, Second Annual Meeting, 1931, p. 52.

In Indiana where there are no full-time health units, the county nurse is the only full-time paid health worker. It is doubly important for her to know both content and methods in sanitation. At this Indiana Sanitation Institute which was attended by 25 public health nurses, great emphasis was placed on the fact that the public health nurse's part in a community sanitary program is chiefly education, and not administration or enforcement of laws.

Far reaching results are bound to come from this institute as illustrated by two letters that have recently come from two of the county nurses who attended. One wrote that she hesitated long before she decided to drive the 100 miles to attend, but she felt more than repaid by the help and suggestions she obtained. Along with her letter she sent an order for 500 copies of bulletins on water, milk, and sewage sanitation, to be used as textbooks in her adult Red Cross Home Hygiene classes.

Another county nurse, working in one of the counties having the highest death rate from typhoid, writes:

I have a lot of ideas I want to put into action that I got from the Sanitation Institute. At my last county nursing committee meeting we started a whispering campaign about sanitary privies. At first the women thought it was very funny, but after we had looked at the maps and graphs and discussed them they decided the matter should not be whispered but fairly shouted.

**The School of Nursing and Fundamental Needs in Public Health Nursing**—Studies have shown that approximately 85 per cent of all sick people are cared for at home, so it is very important that nurses be prepared to adjust themselves to home situations. Nearly all public health workers and private duty nurses work in the homes, and this throws a challenge on the nursing schools to give their students the preventive as well as the curative point of view.

In our present system of nursing education nursing schools, for the most part, avoid the field of preventive medicine in their plan of instruction, probably either because it is not considered fundamental in the training of the nurse or because the instructors and nursing staff are not abreast of the progress in scientific thought. They apparently feel that the nurse who is going to specialize in public health nursing can gain the public health point of view in her postgraduate course. But the nurse should have this before she takes the postgraduate course.

The private duty nurses need the public health point of view also, and since they do not take postgraduate courses in public health nursing they often never obtain it. This is serious, as there is no dividing line between sickness and health and the public expects every nurse to be a health teacher.

If it is important for the nursing school to be concerned about the quality of its health teaching it is just as important for the public health nurses working in a community to inspire and influence the teachers and instructors in the nursing schools along public health lines. Often the public health group isolates itself and fails to take advantage of its opportunities to demonstrate public health needs to the nursing school staff.

The nurse who practises in the home must be skilled in her art. Too many

nursing schools teach the nurse how to do perfect work with the fine equipment in the hospital without showing her how to adapt nursing measures to the different and often inadequate equipment in the home. It is considered desirable to teach home nursing to lay groups, and how much more necessary it is that student nurses be familiar with the course and its practical application!

The care of the sick at home requires a nurse who can teach nursing. The visiting nurse must instruct the family to give nursing care between her visits. The nursing school cannot train her

completely to do this but it can create the right attitude towards teaching as follows:

1. Prepare the nurse carefully in the details of nursing practice, emphasizing the why and wherefore of the procedure and not the mere mechanics.
2. Include in the classroom demonstration procedures applicable to home use.
3. Encourage the student to develop team work in the care of the sick.--

Clara B. Rue, *The School of Nursing and Fundamental Needs in Public Health Nursing*, *Am. J. Nurs.*, XXXII, 3: 311-315 (Mar.), 1932.

## EDUCATION AND PUBLICITY\*

**How Do Local Editors Rate Public Health as a Source of News?**—Can you cite examples of incidents, unusual situations or other experience that would make good newspaper feature stories?

What does the buyer of printing need to know and to do to get the best results from the printer and to cut the costs?

Is the impression made on the reader by your annual report mainly one of quantity of work done or is the quality brought out also?

The above questions are selected at random from "A Brief Course in Social Work Publicity" which was prepared by Mrs. Routzahn for informal study groups of public health workers and social workers. The course consists of outlines for discussion and clinic examples on News Stories, Newspaper Feature Stories, Social Work Case Stories, Appearance of Printed Matter, Annual Reports and Letters and Letter-heads.

If you are interested in organizing a group for a series of from six to ten 1-hour or 2-hour sessions on publicity methods, write to Mrs. Mary Swain Routzahn, Russell Sage Foundation, 130 E. 22d St., New York, for further information.

**Is It a New Idea?**—Health ideas expressed years ago, or methods used in the "once upon a time" have been noted in this department as a reminder that all that is good is not new and original with this generation of public health workers.

Recently several who had been in tuberculosis work 25 years ago held a brief reunion, with several "youngsters" present. One of the latter acknowledged learning that a recently "discovered" publicity method had actually been used in that far off period. This led to the mention of various campaign methods of today which had actually been used 20 to 25 years ago in the first educational campaigns of the National Tuberculosis Assn. One of these was the contribution of paid advertising space. The "whispering" or "talk-

\* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

ing" campaign used by several community chests in the last 2 years was put on in two or three cities 20 years ago. A recently discovered article by one member of the luncheon group, published in 1895, outlined the main elements of the campaign project as it is now conducted for health and other purposes.

The group of oldsters included P. P. Jacobs of National Tuberculosis Assn.; Ernest D. Easton of New Jersey Tuberculosis Assn.; George Nelbach of State Charities Aid Assn.; Evert G. Routzahn, one-time the original educational campaigner of the National Tuberculosis Assn.

**Were You Among the Few or the Many?**—The "few" were those who did send back to the editor of this department the form asking their judgment upon the interest appeal of what appeared in the department. The "many" were most of those members of Public Health Education Section who received that request.

However a single response regarding the February, 1932, issue made the sending worth-while. Some of his 3 pages of typewritten comment will be published. Here is his scoring: "Interesting?" "Yes" for 4 items; "not much" for 3 items; "no" for 4 items (one "ordinarily, yes"; 2 "because we are not mentioned").

After a few more tests we will report the full vote, and some of the topics will be dropped.

**Is It Fair?**—Particularly in these days of close budgeting of postage and printed matter is it fair to mention in reading lists publications intended for distribution to the teachers or to citizens generally in a given city or state? Within a few months one state health department received requests from 22 cities outside the state for supplies of its health educational material. Some

requests went as high as 50 or 100 copies. Nearly every reference list for teachers names some publications to which individual teachers are not entitled. And some department lists suggest that mothers write to departments in other states for specified publications!

**For the Busy Teacher**—The Board of Education of New York City has distributed to its teachers three manuals of unusual conciseness and completeness in detail. Unfortunately the edition is too limited for outside distribution. But we have secured a few sets to be *loaned to those who send the editor of this department 5 cents postage and a promise to return the set in 10 days.*

The general title: *Supplementary Materials And Suggested Activities To Be Used With The Course Of Study And Syllabus In Health Education For Elementary Schools.* There are three separate editions—for grades 1A-3B, 4A-6B, and 7A-8B.

We don't attempt to pass on the teaching values, but as reference manuals they have points especially worthy of mention. Each is brief (14 to 17 pages); stiff cover; a page of "Materials" is faced by a page of "Suggested Activities" for "All Grades," and separately for each specific grade; for every reference to "Material" there is an address, and for nearly every reference there is a price or "free"; the references are grouped under "Teachers," "Children," and "Posters" (so few lists differentiate between background material for teachers and material to be used directly with the pupils); "Starred items form a good minimum library"; double stars indicate "Of unusual value for anyone interested in health education"; 9 items listed are priced at 10 cents to 35 cents, one at \$1.25, *all others are 5 cents or less, or are free.*

Under "Suggested Activities" there are frequent notes in italics, such as

"This activity helps to . . .," "This activity emphasizes . . .," etc. We commend this publication to all who make up reference lists for its conciseness, clearness, accuracy and uniformity in arrangement, all of which help the busy, busy teacher. It was prepared by a committee of special health teachers, under the direction of Dr. I. H. Goldberger, assistant director of health education, with the coöperation of Mrs. Elizabeth Semenoff of the Bronx Tuberculosis and Health Committee and Mrs. K. Z. Whipple of the New York Tuberculosis and Health Association, which agency published the pamphlet.

**They Object to Repeaters**—At the Montreal business meeting of the Public Health Education Section some general policies were formulated as reported below by Chairman Ira V. Hiscock of the Nominating Committee:

The Nominating Committee of the Public Health Education Section, in submitting its recommendations for officers and Council members for the ensuing year, made certain suggestions regarding future policies. It is believed desirable that as the terms of present Council members expire, new Fellows be elected to the Council in order that new viewpoints may be secured regarding program building, section functions and opportunities. It is assumed, however, on the basis of past experience in the section, that former Council members will continue to participate in section activities. Another suggestion was to the effect that there should be no "promotion" plan from one section office to another. In other words, officers should be selected each year on the basis of what, in the judgment of the Nominating Committee, and in the light of circumstances, would promise the most useful working group for the coming year.

**A Public Health Teacher**—One phase of the work of the district health officer described in *Public Health News* (Jan., 1932), New Jersey Dept. of Health:

Public health education is an activity in which the district officer takes an active, personal part. He furnishes the press of his district with facts and news items, gives talks to

interested groups, and arranges for the distribution of literature published by the department. His discussion of public health matters includes tuberculosis as well as the other communicable diseases. He should be a valuable aid in keeping the inhabitants of his district health-conscious and in guiding the public away from the fads, cults, and nostrums, to sound preventive and curative measures.

**What Other Teachers Are Doing**—So far as we know, the "Health and the School" department of *Hygeia*, 535 North Dearborn St., Chicago, is the most accessible record of current actual classroom practice in teaching health. A section of the department reports on "New Health Books and Teachers' Materials." And the body of the magazine carries a wealth of material for all who teach—or speak or write on health topics. Since a free sample copy will be sent upon request we need not go into detail. But we do want to quote the following:

**A Scientific Spirit in Health Education**—After a brief discussion of health superstitions, ancient and modern, the editor, J. Mace Address, says:

The human body has such remarkable vitality and power of adjustment that in many instances it cures itself. To the quack and his followers this leads to the conclusion that many a cure is due to their particular remedy. But science rests on the combined and compared experience of many students who often devote their lives to particular problems. Their findings are checked, tested and tried thoroughly before they are used in the treatment of human ills or in promoting positive health.

Here is a text of much needed popular education. Dr. Address makes the application to the classroom through a description of some new texts from the University of Texas which we have not seen.

#### DIPHTHERIA

"Diphtheria: Michigan Death Rate 1901-1930," *Public Health*, Michigan Dept. of Health, Lansing. Dec., 1931. Effective diagram.

"The Fight Against Diphtheria," editorial. *Journal*, American Medical Assn., 535 N. Dearborn St., Chicago. Review of progress. *Ask for clip sheet*. Free.

"Depression Hits Diphtheria" (lowest previous record in New Jersey practically cut in half in 1931). *Public Health News*, Trenton. Jan., 1932.

The New York City Dept. of Health supplies a diphtheria warning notice for physicians to mail to parents of children under 5 years of age.

#### TRAINING COURSES

Prof. C. E. Turner will give a 6 weeks' summer course in health education at University of Hawaii. Opens June 29.

A course for high school teachers will be given during the spring term at Massachusetts Institute of Technology.

A summer course for teachers of fresh air classes will be given at Teachers College, New York, by Prof. H. G. Rowell and Louise Strachan.

In common with other state tuberculosis associations the Florida Tuberculosis and Health Assn. held three institutes for public health nurses and medical social workers. The first of the series was given in connection with the annual meeting of the association.

"The Illustrated Lecture: Some Do's and Don'ts in Poster and Project Teaching," by L. K. Wolf. *American Journal of Nursing*, 450 7th Ave., New York. Jan., 1932. 35 cents. Illustrative material prepared by the teacher; material prepared by the student; assembling project material; essentials of a good poster; weaknesses of a poor poster.

Those who are concerned with training on the job for public health workers of various types would be interested in "Forthcoming Lectures And Training Courses" in *Mother and Child* (formerly *National Health*), 5 Tavistock Sq., London, W. C. 1, England. In the Dec., 1931, issue were listed courses and lectures given by 14 or-

ganizations ranging from Natl. Assn. for the Prevention of Infant Mortality to Royal Institute of Public Health.

#### LISTS

"Directories of State and City Health Officers, 1931." *Public Health Reports*, Washington, D. C. Dec. 4, 1931.

"State and Local Social Hygiene Societies in the U. S." *Journal of Social Hygiene*, 450 7th Ave., New York. Jan., 1932. 35 cents. Reprint, 10 cents.

"Whole-Time County Health Officers, 1931." *Public Health Reports*, Washington, D. C. Dec. 18, 1931.

#### MOTION PICTURES

1000 and One: The Blue Book of Non-Theatrical Films. *Educational Screen*, 64 East Lake St., Chicago. 8th edition. 144 pp. 75 cents. Classified under 136 headings, including "Physiology, Health and Hygiene." Both 35mm and 16mm. Useful for sanatoriums and other institutions using any non-health film.

Several 16mm motion pictures, including amateur film, will be displayed at headquarters of Social Work Publicity Council, during the National Conference of Social Work, Philadelphia, May 15-21, 1932. *An amateur health film is desired.*

For the first time a sound trailer is offered in addition to the silent trailer for use in the 1932 Early Diagnosis Campaign during April.

Social Hygiene Motion Pictures, by American Social Hygiene Assn., 450 7th Ave., New York. Revised list. Free. Condensed easy reference data. For example:

Title of film (The Gift of Life); Subject (biology of sex and reproduction); Type of film (narrative and diagrammatic); Suitable for use by (teachers and lecturers); For groups of (adults and young people); Synopsis (Under the guidance of a scientist, a boy . . .); No. of reels (4); Purchase price (35mm \$170; 16mm \$120); Rental per day (\$4.00).

Several pictures on milk, milk production, fruits and vegetables, are offered for charges both ways by Motion Picture Service, International Harvester Co., Chicago.

New York. 5 pp. 10 cents. Synopsis of each play and how to secure copies. Includes "From House to House" (visiting nurse), and "My Son John" (mental hygiene).

#### ADDITIONAL DIET MATERIAL

Current background material and material for copy is easily available.

"Food and Health: " A Study of Consumers' Habits, Editorial. *Journal of American Medical Assn.*, 535 N. Dearborn St., Chicago. Feb. 13, 1932.

"Limited Living." *Monthly Bulletin*, Bureau of Health, Rochester, N. Y. Dec., 1931.

"The Bartlett's Beat The Depression." *Health Bulletin*, North Carolina State Board of Health, Raleigh. Jan., 1932.

"How to Feed The Home Folks In Hard Times." *Commonwealth Bulletin*, Health Council, Citizens' Aid Bldg., Minneapolis. Dec. 15, 1931.

"Living Up To The Food Budget." *Connecticut Health Bulletin*, State Dept. of Health, Hartford. Feb., 1932 (radio).

"Emergency Nutrition Special." *American Child Health News*, Jan., 1932. Out of print.

*Journal of Home Economics*, 101 E. 20th St., Baltimore. Feb., 1932. 30 cents. Several articles.

#### PLAYS

A revised edition of *Plays About Social Problems* lists the plays available for adult performers which have come to the attention of the Social Work Publicity Council, 130 East 22d St..

#### SCHOOLS—CHILDREN

Scientific background material is contained in *Health Bulletin For Teachers*, Metropolitan Life Insurance Co., New York. Free.

In one issue of *School Health Bulletin*, Illinois Tuberculosis Assn., Springfield, addresses are given for securing mentioned printed helps; in another issue, no addresses are given for Office of Education and Children's Bureau. Will all teachers remember these addresses?

"Is There a Formula for Sex Education?" introduces several charts used by Professor T. W. Galloway in the last training institutes conducted by him. They outline concisely what children and young people "should acquire," the three parallel columns being headed "In Knowledge," "In Habits," "In Tastes, Preferences and Attitudes." This material is grouped for "the first 6 years of life," "at the age of 12," "during junior high school," "senior high school youth."—*Journal of Social Hygiene*, 450 7th Ave., New York. Feb., 1932. 35 cents. In the same issue: Report of the Sub-Committee on Social Hygiene of the National Conference on College Hygiene," taken from Proceedings of the conference held in May, 1931. Full report published by National Tuberculosis Assn., 450 7th Ave. New York.

## BOOKS AND REPORTS

**Courts and Doctors**—By *Lloyd Paul Stryker*. New York: Macmillan, 1932. 236 pp. Price, \$2.00.

This useful book is the work of a well known lawyer who served for many years as counsel for the New York State Medical Society and as editor of the legal section of the state medical journal. As the result of a rich experience in defending physicians against malpractice suits, in rendering other valuable legal aid to them, and in writing pertinent monthly comments on the subject, the author has constructed an excellent non-technical treatise on law for practising physicians, who are the rank-est of laymen when jurisprudence is involved.

With the exception of a somewhat paternal and rather long-winded introduction, the book is interesting and practical, and it ought to do much to clarify the legal relationships between doctors and their patients.

Since the book contains nothing at all on public health law, sanitarians will find it valuable only if they are also in active private practice. The book is well printed, has an index, and is written in a pleasing conversational style. The references and citations for each chapter are assembled at the back of the book, which makes their utility almost nil.

JAMES A. TOBEY

**Industrial Hygiene for Engineers and Managers**—By *Carey P. McCord, M.D., assisted by Floyd P. Allen, M.D.* New York: Harper, 1931. 317 pp. Price, \$5.00.

The specialist in industrial hygiene has been favored in his reference work by being able to refer to the excellent text of Kober and Hayhurst. This is

now the standard text in the English language for the industrial specialist.

The large group of plant engineers and managers, men who are in vital, everyday need of help in this field, have, however, up to this time, not been so fortunate. The present volume by Dr. McCord and his associate, Dr. Floyd Allen, fills this need of plant officials most admirably.

No longer is industry content to hire men, put them to work under conditions of an adverse or even unhealthy environment, and to discharge them when they are ill or incapacitated.

The present volume clearly brings out the many-sided nature of the problems of industrial hygiene, and shows how these problems may be solved. In the modern factory the worker is given a physical examination after being hired, and is placed at a task for which he is mentally, physically and professionally suited. His environment, as well as the machinery with which he works, is supervised so as to eliminate, in so far as possible, causes of accidents, and the materials with which he is brought into contact are selected so as to avoid the use of poisonous substances, or they are controlled so as to prevent the occurrence of actual cases of poisoning. Dr. McCord and his associate discuss all of these phases of industrial hygiene in a manner which should give the officials of even the very small plant an opportunity to institute the procedures which the larger plant is enabled to obtain by virtue of its more complete functional organization.

Even under ideal conditions, industrial hygienists recognize the occurrence of the "unavoidable" accident, which makes the provision of the emergency

hospital or dressing station a necessity in every plant. In the chapters devoted to the "medical department in industry," "emergency aid," and "bandaging for the industrially injured," the reader is told not "what to do" but actually "how to do it."

Nor is this the complete scope of the volume at hand, for in addition to the above, there are presented well balanced discussions of the rehabilitation of the injured employee, both monetarily (compensation) and physically. Finally, it should be pointed out that the book is written from the preventive viewpoint, a viewpoint characterized by excellently written chapters dealing with accident prevention, protective garments, dental service, the economics of human conservation in industry, food for the industrial worker, and industrial mutual benefit associations. Engineers and officials of large industries will find this volume of inestimable value and the single chapter devoted to "Health Promotion in the Small Plant" should compel the officials of every small plant to own a copy of this book.

LEONARD GREENBURG

**Manchurian Plague Prevention Service Reports, 1929-1930.** *Anti-Plague Institute, Harbin, China, 1931.* 232 pp.

The Manchurian Plague Prevention Service was established directly after the severe plague epidemic in 1910 and 1911 (60,000 deaths). It has been in existence sufficiently long and without interruption by internal chaos to build up an extensive organization with facilities for hospitalization, field investigation, laboratory research, and epidemiological control. During quiescent periods the organization serves the people in the vicinity of its hospitals in ordinary ways. Formerly an independent service, this seventh biennial report announces its absorption into the National Health Administration.

The second extensive plague epidemic occurred in 1920 and 1921 (9,000 deaths). Another was expected at the end of the decade in 1930 and 1931, but failed to appear. The reasons given for this are: the depletion by wholesale hunting of the tarabagan, which species constitutes the animal reservoir of plague, and better precautionary measures taken by the hunters at the instigation of the Plague Prevention Service. Recently when sporadic cases of plague occurred, most of them were of the bubonic type. Formerly the Service had to fight directly the wild rodents in sparsely populated regions, but now, with Manchuria's population rapidly increasing, it has to deal with the ubiquitous rat in crowded settlements as a potential menace.

This report of the 19th year includes a number of scientific papers by members of the Plague Prevention Service on subjects other than plague. One cannot but wonder, while reading this excellent presentation, under what auspices forthcoming reports on plague prevention service will be issued in view of present developments in Manchuria.

W. W. PETER

**Foods in Health and Disease—By Lulu G. Graves.** *New York: Macmillan, 1932.* 390 pp. Price, \$3.50.

This simply and clearly written text is a concise and up-to-date encyclopedia of common foods with data on the nutritive properties of each. The first section, devoted to foods in health, contains descriptions of the various vegetables, fruits, sugars, nuts, animal foods and dairy products, fats and oils, beverages, and food accessories. The second section takes up foods in disease, including such matters as overweight and underweight, infection, nephritis, gout, arthritis, epilepsy, gastrointestinal troubles, diabetes, deficiency diseases, diseases of circulation, and the allergies. Several appendices give tables of vita-

mins and edible organic nutrients. The book is adorned with numerous excellent illustrations and probably as a consequence is printed on a heavy, glossy paper. Each chapter has a bibliography and there is a good index. The book will be of value to all students of viands, victuals, aliments, comestibles, and pabulums. JAMES A. TOBEY

**A System of Bacteriology in Relation to Medicine. Vol. VI.** London: His Majesty's Stationery Office, 1931. 538 pp. Price, \$6.00. Postage extra.

This volume is one of the most interesting of the series so far published. The first chapter considers the relation of bacteria to disease. The other 16 treat of immunity from all angles, beginning with the problems of natural immunity and treating of toxins and every phase of the question which one can think of. It is a comprehensive study of this tremendous and important question, though it does not include all of the knowledge which has been accumulated concerning active immunity, antigens, and antibodies. The first chapter is the only one which can be criticised seriously. It strikes us as inadequate, treating the subject of aggrsins, for example, in an incomplete manner. The last chapter gives a survey of the field of chemotherapy.

The peculiar strength of this volume lies in the enumeration of questions which arise in regard to most of the subject matter. The problems of research in immunology are so numerous and the data often so unsatisfactory that we cannot but value highly the suggestions and analytical approach to their solution here given.

The volume as a whole is excellent, though there is some lack of balance in the various chapters, which are written by different authors, some treating their subjects too briefly and others indulging in unnceary repetition. Excellent but

not exhaustive references to literature are appended to each chapter.

An index would probably add too much to the expense, and one for the entire system will doubtless appear in the last volume, but reading and study of individual volumes would be easier if each had its own, though this is a minor fault, since the Table of Contents gives an excellent analysis of what each chapter contains.

The printing and make-up are excellent. We consider this volume as worthy of those which have gone before, and the whole series as indispensable to any student of the enormous subject which is covered.

MAZŸCK P. RAVENEL

**The Vitamins—By Ethel Browning. M.D.** Baltimore: Williams & Wilkins, 1931. 575 pp. Price, \$10.00.

This is Volume I of a series entitled "Monographs of the Pickett-Thompson Research Laboratory." It not only treats of the biochemistry of the vitamins, but also of the clinical and experimental aspects. For this reason the work will be of interest not only to the student and biochemist, but also to the dietitian and clinician.

The book is divided into 3 main parts: the vitamins in general, the fat-soluble vitamins A, D, and E, and the water-soluble vitamins B and C. The historical sketch is followed by a review of the literature on the origin of the vitamins and the problems relative to their synthesis. Their mode of action is presented as postulated under the theories of hormone action, acceleration of tissue oxidations, maintenance of mineral equilibrium, and regulation of trophic changes. There are few aspects of the vitamin problem that are not adequately presented.

This is no mere compilation. It is exceedingly interesting because it has not merely followed a definite order, but the present conflicting knowledge is

given in a manner to offset completely the usual tedium attending the reading of such a treatise. The widely accepted classification of the vitamins according to their connection with specific disorders of the body has fortunately been followed.

Though this work is fairly complete, it does not include the entire literature, and for that reason the author has added a bibliography which contains references to papers not mentioned in the text, as well as to those that are. A very valuable part of the volume is that composed of tables showing the vitamin content of foodstuffs, which include the B<sub>2</sub> and E.

It is regretted that references in the text are not numbered to correspond with a number in the bibliography, or that the authors in the text are not given their initials. It is often confusing, where authors have the same name, and one has to hunt through a long list to find the desired reference.

The book is most valuable and the work excellently done. The printing is of the best. All interested in this most vital subject are under a debt to the author, Dr. Browning, as well as to the institution which sponsors the publication.

ESTHER W. STEARN

**Malaria Control by Anti-Mosquito Measures**—By Gordon Covell, M.D.  
London: W. Thacker & Co., 1931.  
148 pp. Price, \$2.00.

As the result of extensive experience in malarial countries, the author has given us an excellent account of the measures which have been suggested and tried for the control of mosquitoes. The book is divided into 3 principal parts, taking up respectively protection against bites, against adult mosquitoes, and against larvae, the last of which contains also a consideration of methods adapted to special circumstances. An appendix, which the author rightly considers an important feature of the book,

is the bibliography of 570 references arranged according to the measures considered. The literature of the world has been drawn upon, and it is hard to detect any omissions. The appendix includes anti-mosquito apparatus, oils, poisons, etc., with addresses of high class firms in various parts of the world from which these materials may be bought. The prices are given in Indian money, which will not be of much assistance to readers in other countries.

The book is well arranged, well written, and adequately illustrated. It is decidedly useful and deserves a wide circulation.

MAZŮCK P. RAVENEL

**Health and Social Evolution.** *Halley Stewart Lecture, 1930*—By Sir George Newman, M.D. London: George Allen & Unwin, Ltd., 1931.  
200 pp. Price, \$1.75.

In discursive and easily readable style the author traces the history of the Public Health Service in England. The story, he claims, is social rather than medical; that is, the "progress of the art of medicine is dependent upon the social evolution of the people."

While the book is a sketch rather than a treatise, there is brought home to the American reader strongly, even though implicitly, the escape of the English public health program from bureaucracy, in our subversive American sense, as well as the fact of significant accomplishment. They have attained community of purpose and effort without sacrifice of the individual and of individual choice and initiative.

The public health program is only part of a vaster social program which, taken in its entirety, does not show unalloyed gains nor complete successes in all detail, and some critical estimate of the gains and losses, both observed and potential, is indulged in as a concluding chapter.

Sir George Newman is one of the

most interesting writers on health matters we have today. He has given us a book that can be recommended to all for information as well as entertainment.

ALLEN E. STEARN

**The Control of Tuberculosis in the United States**—By *Philip P. Jacobs, Ph.D.* New York: National Tuberculosis Association, 1932. 416 pp. Price, \$2.00.

Within the last 30 years what other single disease in the United States has produced as much as tuberculosis in tons of literature, sums of money, number of hospital beds, full-time workers or organizations? In view of the importance of the subject and its many ramifications, it is a most difficult task indeed for anyone to acquire sufficient experience and perspective to qualify him to tell the story of the control of tuberculosis in the United States. Yet this is what the author has succeeded in doing.

Against a brief European background, the author very carefully traces the origin of the antituberculosis campaign in the United States. He describes the significant contributions made by pioneer leaders and organizations including the National Tuberculosis Association which was founded in 1904. Fanwise, both horizontally and perpendicularly, the movement has spread to permeate the entire social order with its influence. In 1931 there were in the United States, 1,471 tuberculosis associations and committees, duly organized and constituted for that purpose.

Due recognition is given to concomitant forces other than the organized antituberculosis campaigns which have been factors in the actual decrease of the incidence of tuberculosis in this country. Health workers in fields other than tuberculosis are often prone to forget the helpful influence of this strongly organized antituberculosis movement because it has come to be so much taken

for granted that tuberculosis is decreasing where there is no organized movement against it. The debate is not at that point. The question is, how much faster has been the decline because of organized efforts against its inroads.

Very illuminating is the author's presentation of the Christmas Seal sale, its origin, its development to where its returns in 1930 were 5½ million dollars. The author shows intimate knowledge of the development of the Community Chest movement in the United States to the point where now 300 communities are so organized. He discusses the relationship between the Christmas Seal sale and the Community Chest movement.

The book is divided into 4 parts. There are 4 chapters on the historical aspects of the antituberculosis movement. There are 17 chapters on the methods and programs in the control of tuberculosis in the United States. Four chapters are devoted to the fundamental policies of the tuberculosis movement in the United States, and 6 chapters to illustrative programs. There is a list of selected references at the end of each chapter. The author has screened the literature and gives a list of books for the tuberculosis secretary. There are lists also for the nurse, for the physician, and for the tuberculosis patient. The appendix closes with a list of periodicals for those interested in the subject of tuberculosis. Finally there is a good index.

During the 24 years devoted to tuberculosis work, Dr. Jacobs has written a great deal. This concise and comprehensive contribution will probably rank as his most important. This book should be in every public and professional library, particularly in medical and nursing schools. Many physicians, many nurses and most public health and social workers will find it invaluable in the professional health field. This book should be classed as one of the books of the year. W. W. PETER

**Medical Supervision and Service in Industry.** *Compiled and published in 1931 by the National Industrial Conference Board, Inc., 247 Park Avenue, New York.* 125 pp. Price, \$2.00.

This is a revision of two previous studies published by the National Industrial Conference Board, and has the advantage of comparing statistics previously compiled with important new material.

A special feature of the study is the inclusion of 53 per cent of the companies employing less than 1,000 employees.

As the monograph states,

A gradual shifting of emphasis from the curative phases of medical care to preventive work and health education is evident. With this development have come corresponding changes in the personnel and equipment of medical departments and in the average cost per employee. Aside from the sociological benefits resulting from the improved medical care of the employees, there has been a reduction of compensation costs and of waste involved in excessive labor turnover, absenteeism, and low labor efficiency.

The chapter headings indicate fairly well the scope of this publication: "The Place of the Medical Department in Industry," "Staff and Equipment," "Physical Examination of Employees," "Industrial Accidents and Their Treatment," "Diagnosis, Treatment, and Prevention of Illness," "Medical Work in the Small Plant," "Medical Records," "Analysis of Work of Medical Department," "Cost of Medical Supervision and Service," "The Value of Medical Work in Industry."

A valuable addition is the appendix, which includes routine and standardized procedures in physical examinations, first aid treatment, a standardized medical terminology, and last but not least the estimated value of medical service in a company of 500 employees.

This is a valuable reference work for

all who have to do with industrial health and safety in any of its aspects.

C. O. SAPPINGTON

**Ronald Ross. Discoverer and Creator—By R. L. Megroz.** *London: George Allen & Unwin, Ltd., 1931.* 282 pp. Price, \$3.75.

There is no medical man living whose life, history, personality, and accomplishments are more interesting than the subject of this work. He is well described as "a many sided genius," but is best known to the world for his demonstration that the *Anopheles mosquito* is the carrier of the malarial parasite. Over this question has raged an unfortunate controversy. The reviewer believes that the evidence supports the claims of Ross. This was evidently also the belief of those in charge of the Nobel Prize in Medicine, which was given to him in 1902. The verses written on the day of his discovery, amended and sent to his wife the next day, have always seemed conclusive evidence of this stand.

The book before us consists of practically two parts: one devoted to Ross's history and scientific work, the other to his literary accomplishments. Few people realize that, in addition to being a bacteriologist and naturalist of a very high order, he is also a poet, novelist, and mathematician. An introduction to the volume by Osbert Sitwell gives high praise to his literary ability; yet the public knows little about this side of the man.

The first part of the book is not only a history of Ross, but of necessity gives also the story of malaria, and enables one to realize what Ross's discovery has done for the world, showing how justly he estimated his discovery in the verse, "I know this little thing a myriad men will save." The volume closes with several appendixes, the first of which might well have been omitted, as it is Ross's answer to the claims of Grassi,

not written in the best temper. The others are bibliographies of his scientific publications, those on mathematics and literature, and finally a list of his awards and honors.

The book is well written. Every page holds the reader, even though he may not be a scientist and acquainted with Ross's accomplishments. A peculiar pathos attaches to the book, appearing at a time when Sir Ronald is in dire straits financially, after a life devoted to the welfare of the public and crowned with success recognized throughout the world. It tells of his grinding work, heart burning disappointments, due to orders from those in authority—for he was an army man—coming at the moment when success seemed imminent; of the claims of others which would have deprived him of the credit so richly deserved.

The author is frankly a hero worshipper when it comes to the subject of his work.

We commend this book to the public and even to those physicians and bacteriologists who have read Ross's *Memoirs*. We trust that it will bring to England a realization of the claims of one of her foremost scientific sons who we believe has not received the recognition due. MAZŸCK P. RAVENEL

**A System of Bacteriology in Relation to Medicine. Vol. IX. London: His Majesty's Stationery Office, 1931. Price. \$6.00.**

This is Volume IX of the System of Bacteriology in Relation to Medicine published under the auspices of the Medical Research Council of England. It is devoted to technical methods, and includes the general index. The authors do not pretend to give all of the useful methods of doing bacteriological examinations, but describe one or more

for each procedure which they have found adequate for their own needs. It is unfortunate that they have not seen fit to include more of the well known American and continental European procedures. In this country, the direct titration of mediums to a desired pH by the use of bromthymol blue has almost entirely replaced the indirect methods in which thymolphthalein or phenolphthalein is used.

To one trained in immunology, it is not entirely clear how the results of the Wassermann test, described on page 208, can be read, "when some of the tubes are quite laked and others are quite opaque," especially in a series of negative tests.

In addition to chapters treating of the usual bacteriological methods, there are others which give details of technic not so well known to many bacteriologists as: isolation of single bacterial cells; filtration; methods of studying filtrable viruses, including their cultivation, preservation, and the demonstration of cell inclusions; the measurement of oxidation-reduction potentials; the determination of electric charge; and the production and isolation of bacterial variants. The chapter on Production of Variants is especially interesting. Of great practical value are the directions for breeding, maintenance, and handling of laboratory animals.

This volume is a fitting ending for the most valuable series which has preceded it. It shows the study and discriminating judgment which characterize all other volumes of the series. The printing and make-up of the book are exceptionally good. Bacteriologists the world over are under a debt of gratitude to the Medical Research Council as well as to the individuals who have done the actual work in the production of these volumes. NEWELL R. ZIEGLER

# A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

**Canadian Opinion on Maternal Mortality**—This summary of the various answers to a questionnaire on the causes and prevention of maternal mortality reveals only that there is little difference in the number and variety of opinions on this subject north and south of the international line.

BROWN, J. N. E. *Observations and Opinions on Maternal Mortality.* Canada Lancet, 78, 4: 108 (Apr.), 1932.

**Pneumonia Type II**—In a study of 1,000 cases with a mortality rate twice that of type I, Felton's serum was found beneficial, though not strikingly so.

CECIL, R. L., AND PLUMMER, N. *Pneumococcus Type II Pneumonia.* J. A. M. A., 98, 10: 780 (Mar. 5), 1932.

**Longevity in Mental Deficiency**—If one wishes to know how long idiots, imbeciles and morons live, what their expectancy is in relation to total population, and of what they die, this paper will prove a gold mine of information.

DAYTON, N. A., *et al.* *Mortality and Expectation of Life in Mental Deficiency in Massachusetts: Analysis of the Fourteen-Year Period 1917-1930.* New Eng. J. Med., 206, 11: 555 (Mar. 17), 1932.

**The Dangers of Childbirth**—The terrified expectant mother who reads this "penny dreadful" will decide that she might as well be taken out behind the barn and shot as to brave the dangers of modern obstetrics. A good example of a popular article with considerable factual basis which produces a thoroughly undesirable and unwarranted end picture.

DEKRUIF, P. *Savers of Mothers.* Ladies Home J., Mar., 1932, p. 6.

**New York Health Centers**—The importance and value of statistics in health center planning is excellently

illustrated in the discussion of the problem of providing local health services to a group of 7 million people living in an area of more than 300 square miles with a population density varying from 2,000 to 84,000 per square mile.

DROLET, G. J., AND WEINER, L. *Vital Statistics in the Development of Neighborhood Health Centers in New York City.* J. Prev. Med., 6, 1: 59 (Jan.), 1932.

**Pollution of Water Supplies**—Numerous examples of the way pollution has entered presumably safe deep-well water supplies are presented in graphic detail.

EASTWOOD, C. H. *Pollution Hazards.* Water Works Eng., 85, 5: 248 (Mar. 9), 1932.

**Typhoid Fever Vaccination**—Persons who have had typhoid fever or prophylactic treatment produce more antibodies in response to subsequent inoculations than do those who have not; the ordinary routine treatment may not produce as much immunity as we have believed; and the severity of the reaction bears no relation to the immunity produced.

FEEMSTER, R. F. *The Effect of Typhoid Fever and of Previous Typhoid Vaccination on the Antibody Response to Inoculation with Typhoid Vaccine.* J. Infect. Dis., 50, 2: 120 (Feb.), 1932.

**Dust Sampling**—The impinger dust sampler is described in detail and its use explained. It is of value not only in the collection of dust particles, but for certain fumes as well.

GREENBURG, L., AND BLOOMFIELD, J. J. *The Impinger Dust Sampling Apparatus as Used by the U. S. Public Health Service.* Pub. Health Rep., 47, 12: 654 (Mar. 18), 1932.

**Organized Health Propaganda in England**—What the Central Council for Health Education proposes to do in

its advisory capacity concludes a stimulating discussion of the whole field of influencing health behavior.

KENWOOD, H. R. The Health Education of the Citizen. *J. State Med.*, 40, 3: 126 (Mar.), 1932.

**Convalescent Serum in Poliomyelitis**—"We failed to obtain statistical evidence that convalescent serum is effective. However, it is not possible to draw the reverse conclusion; namely, that serum is of no value." The authors feel that the study reported justifies its use on a larger scale.

KRAMER, S. D., *et al.* Convalescent Serum Therapy in Preparalytic Poliomyelitis. *New Eng. J. Med.*, 206, 9: 432 (Mar. 3), 1932.

**Climate and Health and Fecundity**—Argument: if storms stimulate metabolism, then goiter, anemia, diabetes, and mental diseases should be overstimulated. Sure enough, proportionate deaths from these conditions are greater in the "storm country" than in the south. You draw your own conclusions about whither we are drifting. The same storms stimulate female fecundity, concludes the author upon statistical evidence which seems a bit thin.

MILLS, C. A. Climate as a Factor in the Health of Man, and Geographic Variations in Female Sex Functions. *Am. J. Hyg.*, 15, 2: 573 (Mar.), 1932.

**BCG Vaccination Again**—The reasons why the author considers BCG unsafe are set forth. He includes the Lubeck disaster, offering it as evidence of reversion, because in his opinion contamination with human tuberculosis did not take place. Since his paper was written the trial findings have been published and the principals are convicted of negligence in permitting the possibility of just such contamination.

PERROT, S. A. The Present Status of BCG Vaccination. *New Eng. J. Med.*, 206, 9: 436 (Mar. 2), 1932.

**Venereal Disease Trends**—Two state-wide surveys of venereal disease incidence in 1927 and 1930 produced some interesting findings. The crude statistics indicate no change in the trend of gonorrhea and a slight increase in syphilis. Only 20 per cent of the physicians thought the diseases were increasing, and they believed this to be caused by moral laxity, prohibition, better diagnosis, ignorance, and uncontrolled prostitution. Those who thought the diseases to be decreasing gave as the reasons education, prophylaxis, better treatment, and clinics.

PFEIFFER, A., AND CUMMINGS, H. W. Syphilis and Gonorrhea in Up-state New York. *Am. J. Hyg.*, 15, 2: 459 (Mar.), 1932.

**Dissociation and the Staphylococcus**—*Staphylococcus albus*, *citreus* and *roseus* may be split off from *S. aureus*, and *aureus* in turn may be recovered again from *albus*. The authors find the *aureus* and *albus* strains essentially similar to S and R strains in other bacteria. Thus is another prop pulled out from under our shaky temple of bacteriological beliefs.

PINNER, M., AND VOLDRICH, M. Derivation of *Staphylococcus Albus*, *Citreus* and *Roseus* from *Staphylococcus Aureus*. *J. Infect. Dis.*, 50, 3: 185 (Mar.), 1932.

**Gas Appliance Ordinance**—Both the provisions of the Baltimore gas appliance ordinance and the problems concerned in its enforcement are discussed in detail.

SCHULTZE, W. H. The Baltimore Gas Appliance Ordinance and Its Relationship to Public Health. *J. Indust. Hyg.*, 14, 2: 41 (Feb.), 1932.

**Hemolytic Streptococci in Milk**—The term "*St. epidemicus*" cannot be used to designate the causative agent for septic sore throat, say these authors. Milk-borne sore throat and scarlet fever may be caused by one of several types of hemolytic streptococci.

WILLIAMS, A. W., *et al.* Milk-Borne Septic Sore Throat and Scarlet Fever and Their Relation to Beta Hemolytic Streptococci. *J. Bact.*, 23, 3: 241 (Mar.), 1932.

**More About Russia**—Among the very few unprejudiced glimpses we get into the Russian scene, this will be particularly interesting to health workers, for it has to do with social problems nearest to them.

WILLIAMS, F. E. Russia—A Nation of Adolescents. *Survey Graphic*, 46, 1: 9 (Apr. 1), 1932.

**Getting the Most Out of Health Examinations**—The school health examination becomes an educational ex-

perience when all the possibilities are realized in anticipation, preparation, examination and follow-up.

WILSON, C. C. Making the Health Examination an Educational Experience. *J. Health & Phys. Ed.*, 3, 3: 8 (Mar.), 1932.

**Communicable Disease Fatality Rates**—Case-fatality ratios less than these indicate incomplete reporting: diphtheria 15 to 19 cases to 1 death; measles 500 to 1; scarlet fever 100 to 1; typhoid fever 8 to 12 to 1; whooping cough 125 to 150 to 1. This is the conclusion of a Pennsylvania study.

WOOD, H. B. Case Fatality of Communicable Disease. *J. Prev. Med.*, 6, 2: 87 (Mar.), 1932.

# NEWS FROM THE FIELD

## SUMMER SCHOOL COURSES IN PUBLIC HEALTH

*While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.*

*University of California, Berkeley, Calif.*

June 23–August 3

Administration of Schools of Nursing  
Elementary Epidemiology  
Elementary Public Health  
Public Health Nurse in Relation to the Community  
Responsibility of the Public Health Nurse for the Health of the Adult  
Elementary Supervision in Schools of Nursing  
Advanced Supervision in Schools of Nursing  
Biometry

*University of Chicago, Chicago, Ill.*

June 20–August 26

First Term: June 20–July 22

Second Term: July 25–August 26

Teaching the Principles and Practices of Nursing  
Supervision in Schools of Nursing  
Field of Public Health Nursing  
General Bacteriology  
Advanced Bacteriology, Parasitology, and Public Health  
Special Public Health Problems  
Preventive Medicine and Immunology  
Introduction to Nutrition and Dietaries  
Nutrition and Diet in Disease  
Clinical Nutrition  
Readings in Nutrition  
Child Care  
Child Development and Training  
Nutrition Work with Children  
Principles and Problems of Human Nutrition and Dietetics

*Columbia University—DeLamar Institute of Public Health, College of*

*Physicians and Surgeons, New York, N. Y.*

June 13–July 1

School Health Supervision—Medical Inspection, Mental Hygiene, and Physical Education

*Teachers College, New York, N. Y.*

July 5–August 12

Administration of Health Work in Schools  
Child Hygiene  
Health Care of Infants  
Health Education in Elementary Schools  
Health Problems in the Teaching of Fresh Air Classes  
Home and Community Hygiene  
Industrial Hygiene  
Methods of Teaching Lip-Reading  
Nutrition and Health  
Personal Hygiene  
Principles of Health Administration  
Principles of Public Health Nursing  
Public Health Administration  
Research in Child Health  
Safety Education  
School Nursing  
Sight Saving Classes  
Supervision in Public Health Nursing  
Supervision of Health Education  
Survey of Public Health Nursing

*Cornell University, Ithaca, N. Y.*

July 11–August 19

Gymnastics and Dancing  
Health Supervision of School Children  
Hygiene of the School Child and Adolescent  
Measurements of School Children  
Physical Education

*Duke University, Durham, N. C.*

June 14–July 22

Materials and Methods in Health Education  
Materials and Methods of Physical Education

*University of Georgia, Athens, Ga.*

June 13–August 13

Behavior Problems in Children  
Child Care and Training  
Child Development  
Child Study and Parent Education  
Development of the Young Child  
Diagnosis and Treatment of Exceptional Children  
Educational Biology  
Educational and Mental Hygiene  
Educational Hygiene  
Educational Sociology  
Health Education  
Mental and Educational Measurements  
Physiology and Health  
Play Activities  
P. T. A. and Parent Education  
Principles of Health and Recreation  
Mental Hygiene  
The Age of Adolescence  
The Age of Childhood

*Harvard University, Cambridge, Mass.*

July 6–August 16

Principles and Problems of Hygiene, and  
Teaching Methods  
Physical Education, Theory and Practice

*University of Hawaii, Honolulu, T. H.*

July, 1932

#### EDUCATION ASSOCIATIONS HEALTH SECTION TO MEET IN HONOLULU

THE Health Section Meetings of the Pacific Regional Conference of World Federation of Education Associations will be held in Honolulu, July 25-30, 1932. C. E. Turner, Dr.P.H., of the Massachusetts Institute of Technology, is Chairman. Subjects to be discussed include: Nutritional Needs in Relation to Racial and Climatic Conditions, The Health Examination of School Children, Play Activities in Relation to Health, and Health Training for Teachers. Summer courses in Health and Education will be given at the University of Hawaii in July.

This is an opportunity for participation in an international professional meeting, and for an ideal summer vacation. Special travel rates will be available. For further information write to the Secretary, Sally Lucas Jean, 200 Fifth Avenue, New York, N. Y.

#### SOUTHERN CALIFORNIA ASSOCIATION ELECTS OFFICERS

THE following officers were elected at the recent meeting of the Southern California Public Health Association: President, Wilson G. Knowlton; President-Elect, Dr. W. B. Wells; First Vice-President, Dr. Charles W. Decker; Second Vice-President, Dr. George H. Roth; Secretary-Treasurer, F. D. Sweger.

#### INTERNATIONAL ASSOCIATION OF ICE CREAM MANUFACTURERS

FRED RASMUSSEN, of Harrisburg, Pa., Executive Secretary of the International Association of Ice Cream Manufacturers for the last 7 years, died on February 21. He was 56 years of age, and a native of Denmark, but in 1912 he became a citizen of the United States. Mr. Rasmussen was Pennsylvania State Secretary of Agriculture 1919-1923.

During the War he had charge of work in connection with animal husbandry for the U. S. Food Administration in Pennsylvania and served later in the American Red Cross in France.

Robert C. Hibben, who has been with the Association as head of the Bureau of Service and Statistics for the past 6½ years, has been appointed Acting Executive Secretary.

#### SCHOOL LIFE IN PORTO RICO

MEALS at 1 cent each, payable in produce when cash is not available, are served every day to 50,000 children in the schools of Porto Rico. The meals are prepared and served by girl pupils as part of their school training.

Theodore Roosevelt, in his last written review of education in Porto Rico, before his recent appointment by President Hoover to the governorship of the Philippine Islands, cites this as one of the many methods used in Porto Rico to "disseminate practical knowledge." —*School Life*, official organ of the Office of Education, U. S. Dept. of the Interior.

#### 50,000 SCHOLARSHIPS IN UNITED STATES

INFORMATION regarding scholarships and fellowships available at institutions of higher learning in the United States, which is of vital interest to many thousands of students who need financial assistance to enable them to complete their education, is contained in a new bulletin of the Federal Office of Education, 1931, No. 15, price 30 cents, available from the Superintendent of Documents. The publication, prepared by Ella B. Ratcliffe, chief educational assistant in the division of colleges and professional schools, lists the scholarship offerings at 402 colleges and universities. More than 50,000 scholarships and fellowships are available annually in the United States, it is estimated. The total money value of the grants is approximately \$10,000,000.

## THE LUEBECK DISASTER

IN our issue of March, 1932, we gave the decision of the court concerning the Luebeck disaster finding that Drs. Deycke and Alstaedt were guilty of homicide and sentenced to prison, one for 2 years and the other for 15 months. Most recent reports say that the case has been appealed. The result will be awaited with interest. The sympathy of everyone goes out to Dr. Deycke and his assistants, and we cannot help hoping that some amelioration may be granted on their appeal.

## PERSONALS

DR. JOHN B. DERRICKSON, of Frederica, Del., has been appointed director of the Sussex County Health Unit, with headquarters at Georgetown, Del.

DR. HYMAN I. SPECTOR, member A. P. H. A., of St. Louis, Mo., who resigned 6 years ago as tuberculosis controller for the city, has been reappointed to that position, to succeed the late Dr. Howard H. Bell.

DR. ROBERT R. ELLIS, of Kirksville, Mo., has been appointed deputy state Health Commissioner for a term of 3 years.

DR. JACOB L. MORENO has been appointed Consultant in Psychiatry and Criminology by the Board of Directors of the National Committee on Prisons and Prison Labor.

DR. JUNIUS B. HARRIS, of Sacramento, Calif., and Gifford L. Sobey, of Paso Robles, Calif., were recently appointed members of the California Department of Public Health, to succeed Drs. Robert A. Peers and Fred F. Gundrum, whose terms expired.

DR. FINIS C. SUGGETT, member A. P. H. A., of Columbia, Mo., is the new director of the Des Moines, Ia., County Health Unit. He succeeds Dr. Carl F. Jordan, who is returning to the University of Iowa as assistant professor of hygiene and preventive medicine.

## CONFERENCES

May 9-10, American Association of Medical Milk Commissions, and the Certified Milk Producers' Association of America, New Orleans, La.

May 14, Texas Beach and Pool Association, Fourth Annual Short School, Dallas, Tex.

May 10-15, Annual Congress of The Royal Institute of Public Health, Belfast, Ireland.

May 12-13, Annual Pennsylvania State-wide Safety Conference, Harrisburg, Pa.

May 15-21, National Conference of Social Work, Philadelphia, Pa.

May 20-21, National Advisory Health Council of the National Institute of Health, Washington, D. C.

May 25-27, The Canadian Public Health Association, 21st Annual Meeting, in association with Ontario Health Officers' Association, Toronto, Ont.

June 2-3, State and Provincial Health Authorities of North America, Washington, D. C.

June 2-3, State and Territorial Health Officers Conference, Washington, D. C.

June 6-9, National Tuberculosis Association, Colorado Springs, Colo.

June 9-11, Third Annual Meeting, Western Branch, American Public Health Association, Denver, Colo.

July 9-16, Royal Sanitary Institute, Brighton, England.

July 21-29, 100th Anniversary Meeting, British Medical Association, London.

July 25-30, Regional Conference of the World Federation of Education Associations, Honolulu, Hawaii.

July, 1932, The Second International Conference of Social Work, Frankfurt.

October 24-27, 61st Annual Meeting, American Public Health Association, Washington, D. C.

### Physical Impairment Among One Thousand Negro Workers\*

FLOYD P. ALLEN, M. D., F. A. P. H. A.

*Public Health Federation, Cincinnati, O.*

TWO years ago at the annual meeting of the Industrial Hygiene Section, we presented a summary of our findings dealing with the first of a series of Life Conservation Studies: Physical Impairment among 1,000 White Male Office Workers.<sup>1</sup> Last year we reported before this section on the second group in this series under the title: A Report on 1,000 Physical Examinations of (White) Machine and Hand Tool Operators.<sup>2</sup> In the interim a third group: 1,000 Negro Factory Workers, has been examined. We are presenting in this report some of the more important findings derived in the study of the negro factory workers group.

Procedures attending examinations and subsequent steps in tabulating data for the 3 groups have been followed with a minimum of variation in order that the findings might be trustworthy of comparison. As these studies have progressed, a few items have been added to the physical examination schedule each year, but the basic standards for physical measurements and defections<sup>†</sup> have been precisely followed throughout the series.

The circumstances under which the present study was undertaken were somewhat different from those of either of the preceding ones. It was the outcome of particular concern on the part of the Public Health Federation and the Anti-Tuberculosis League of Cincinnati in the health of the negro. These organizations, desiring to learn more

<sup>†</sup> See *Statistical Report* for plan and purposes of the Life Conservation Series. Standards will be found in Appendix II of statistical report. Copies of this report may be obtained from the Heart Council, 312 West Ninth Street, Cincinnati, O.

about the health of the negro in industry and seeing through the Heart Council's Life Conservation Series an opportunity for scientific study, decided to coöperate in conducting the examinations of 1,000 negro men in industry through the Heart Council.

The group under consideration comprised 1,032 negro men all of whom voluntarily submitted themselves for examination. They were drawn from the rank and file of those employed in the manufacture of metal products, roofing, cotton products, chemical fertilizer, leather goods, and glass products. Thirteen factory groups in the Cincinnati metropolitan area were included in this survey. Our only requirement of examinees was that they be 20 years of age or over.

We have been particularly interested in determining through this series of studies factors involved in the heart disease situation common to later years of life. It has been our desire, therefore, to select a large proportion of men past 40 years in each group. In the clerical group only did we succeed to any extent. Here three-fourths of the men were between 30 and 55. In the white industrial workers group, on the other hand, three-fourths of the men were under 45, and in the negro factory workers group, more than three-fourths (79.8 per cent) were under 45. In spite of our efforts to include older men in these groups, we failed for the reason that they are not to be found in large numbers in industrial work in Cincinnati.

#### GENERAL CONSIDERATIONS

In order that the findings may be given a proper background, it is worthwhile to consider briefly some of the social, economic, and health aspects of negro life in Cincinnati. The negro industrial worker, like others employed in industry, spends two-thirds of his time in an environment common to other members of his family, and it is to this period, aside from working hours, that we must charge many of the ills that befall him.

In the last 10 years Cincinnati's negro population has increased from 7 to 11 per cent, due in large proportion to an influx from southern states. Practically none come to jobs awaiting them; they must seek employment, and the wage scale of those employed is in general low. A considerable number of negroes are to be found idle at any time. Fully 90 per cent are sheltered under conditions of over-crowding with meager facilities for sanitation and comfort. Most of their small earnings are spent for foods and luxuries. Many exist on grossly imbalanced diets, and even though a family of 5 may be living in one room, a radio will usually be found among the furnishings and a dilapidated automobile somewhere near the dwelling. Clothing is often in-

adequate to protect against the cold and dampness. Medical attention is usually sought as a means of cure rather than prevention, even though clinic facilities are accessible either without cost or for a small fee.

The average negro is a care-free sort of person who gives little thought to the future so long as he feels well, has plenty to eat, a place of shelter, and can indulge in the social life of his choice. It is in all likelihood this method of living, with little thought of restraint and less concern about the ill-effects, that accounts for the inception of many of the physical ills to which negroes fall heir. From what information we have been able to gather, we are inclined to believe that with a knowledge and effective application of personal hygiene in a favorable environment, this race can materially lower its morbidity and mortality rates to the point where they will compare favorably with those of the white population. It is not likely, in our opinion, that racial susceptibility or some other unidentified factor can account for excessive morbidity and mortality rates among negroes from certain well known causes.

The mortality experience from tuberculosis during 1930 in two contiguous census tracts in Cincinnati, each with a considerable negro population, shows an interesting contrast. In tract 36, in the group of 4,131 negroes of a poor class, the mortality rate from tuberculosis was 290 per 100,000 population. In tract 37, there were no deaths from tuberculosis among its negro population of 1,763, which is made up of the highest class of negroes in the city.

As a further example, by way of contrast, let us compare the mortality rates for certain principal causes during 1930 among a poor class of whites in tract 5, with those for a high class of negroes in census tract 37:

TABLE I

MORTALITY RATES IN 1930 FOR WHITE POPULATION IN CENSUS TRACT 5, AND FOR  
COLORED POPULATION IN TRACT 37, CINCINNATI

	White rates, Tract 5 per 100,000	Col. rates, Tract 37 per 100,000
Tuberculosis (all forms) .....	673	0
Cardiovascular diseases .....	300	965
Pneumonia .....	224	170
Cancer .....	75	340
Apoplexy .....	150	170
Nephritis .....	139	170
Deaths under 1 year per 1,000 live births ...	172.4	71.4
Diarrhea and enteritis under 1 year per 1,000 live births .....	103.5	35.2

In Table I it will be noted that mortality rates for diseases common

to older age groups are consistently higher for negroes. On the other hand, rates for causes more common to or exclusively among younger age groups are notably lower for negroes. There is in this experience an indication that, through more favorable conditions of living and through proper enlightenment, mortality among negroes can be materially lowered.

#### EXAMINATION FINDINGS—1,000 NEGRO WORKERS

Those negroes drawn for purposes of our study out of the mass employed in Cincinnati industries represent in the main the poorer classes. In the course of examining these men we anticipated that in the aggregate a high per cent of physical defection would be found. Actually, only 1 out of the 1,000 men was considered to be essentially free of physical defects. To many a physical examination was a new experience. The striking fact was that out of 999 men with defects, only 8 knew or admitted knowing of their existence prior to the examination. In the opinion of the examiners, 911 of the group would profit by early medical care. For purposes of summarizing, physical defects were classed as major or minor.\* Examinees with major defects outnumbered those with minor nearly 10 to 1. Among those 25 years of age and under, 87.5 per cent had major physical defects which increased in frequency up to 50 years. Beyond 50 years, all men examined were found to have major physical defects.

Space will not permit entering into the discussion of all the items listed in the tabulation of physical findings. We shall therefore consider only those dealing with cardiovascular lesions and correlations, and pulmonary findings.

#### CARDIOVASCULAR LESIONS

One of the most striking situations in the group of 556 men with significant cardiovascular abnormalities was the high incidence of hypertension, 249, a conspicuous number of whom were under 40. Up to 30 years, 13.8 per cent of all men examined, and between 30 and 40, 21.5 per cent had elevated blood pressures. The curve by age for incidence of hypertension in this group is higher for men over 30 years than those based on insurance statistics and on findings in other similar surveys that have come to our attention. Second readings on a fair sample of examinees (120) previously found to have elevated blood pressures gave when correlated with first readings a fairly high index of reliability of the initial records, viz.,  $0.717 \pm 0.03$  as the probable error.

TABLE II

SUMMARY OF PHYSICAL FINDINGS—1,000 NEGRO FACTORY WORKERS

	No. involved
Weight	
10 lb. or more overweight .....	358
10 lb. or more underweight .....	275
Vision	
20/30 or more in one or both eyes .....	508
Dental defects .....	787
Defective hearing .....	107
Enlarged thyroid .....	39
Significant cardiovascular lesions .....	556
Cardiac enlargement .....	249
Valvular lesions .....	125
Myocardial insufficiency .....	68
Hypertension .....	249

Glycosuria .....	4
Wassermanns positive .....	300 †

\* Findings incomplete.

† Estimated on basis of 83 positives (+++ and ++++) out of 362 Wassermanns obtained.

*Weight and Cardiovascular Lesions*—In our Life Conservation Series totalling thus far 3,000 men, there has been a consistently greater incidence of cardiovascular impairment among those overweight. In the negro group, this relation is shown in Figure I. In this group,

FIGURE I

WEIGHT AND CARDIOVASCULAR ABNORMALITIES  
IN  
1,000 MALE NEGRO FACTORY WORKERS

among men under 40 years, the greater the amount of overweight, the higher the incidence of cardiovascular abnormalities found—as re-

vealed in Figure II. Over 40 years there appeared to be little relation between weight status and cardiovascular abnormalities.

FIGURE II  
OVERWEIGHT AND CARDIOVASCULAR ABNORMALITIES  
IN  
1,000 NEGRO MALE FACTORY WORKERS  
UNDER AND OVER 40 YEARS

Again it was observed, as in the previous two groups, that hypertension existed among more men who were overweight than among those of other weight status. Of examinees 20 lb. or more underweight, 14.8 per cent had elevated blood pressures, 22 per cent within 10 lb. of normal weight were similarly involved, while of those 20 lb. or more overweight, 39.5 per cent were found with high blood pres-

FIGURE III  
WEIGHT AND ABNORMAL BLOOD PRESSURES  
IN  
1,000 MALE NEGRO FACTORY WORKERS

tures. The incidence of abnormal blood pressures and weight status is shown in Figure III.

*Urine Findings and Cardiovascular Lesions*—Not only have these relations between overweight and cardiovascular lesions been noted, but the incidence of albuminuria has been consistently higher among men with cardiovascular lesions. The frequency with which albuminuria was determined for the negro group was notably high.

TABLE III  
ALBUMINURIA AND CARDIOVASCULAR LESIONS  
IN  
3,000 MALE INDUSTRIAL WORKERS

Groups Examined	Rate per 1,000 with Albuminuria among those:	
	With no cv. lesions	With cv. lesions

II. White machine and hand tool operators .....	3.6	6.1
III. Negro factory workers .....	13.4	20.0

The outstanding communicable disease problem among Cincinnati negroes is tuberculosis, which led all other causes of death during 1930. Of all colored deaths from tuberculosis in this period, 22 per cent occurred under and 78 per cent over 20 years of age. Tuberculosis is not only claiming more victims past 20 years than formerly, but the highest incidence of mortality is advancing into age groups around 40 years.

It might be surmised that the incidence of tuberculosis in male negro labor groups would be low because few with the disease could long endure the physical strain, but this disease does exist to an appreciable extent among this type of workers. The Anti-Tuberculosis League of Cincinnati has completed chest X-ray examinations upon 280 negro factory workers and in 2 definite evidence of active tuberculosis was revealed, while in 11 others the disease was suspected—an incidence of 7 per 1,000 with active tuberculosis, and 39 per 1,000 suspected of having the disease. Below 40, the X-ray revealed 31.5 per cent of the 280 men with some form of pulmonary pathology, and over 40 years 43 per cent were involved. The average age where tuberculosis was either found or suspected was 37 years.

This study is at present limited. The Anti-Tuberculosis League hopes to increase the series of X-rays to involve at least 500 of the men originally examined. From what has been learned in our contact with negroes, with this group as a whole and the roentgenologic studies of it in part, we believe that tuberculosis must not be overlooked as a source of physical impairment in dealing with the industrially employed negro.

GENERAL COMMENT

Among 1,000 male negro industrial workers, only 1 was found to be essentially free of physical defects, and for the remainder, major defects predominated. In view of this situation, we wonder how these men can endure moderate to great amounts of physical effort exacted of them. As a matter of fact, many do not long endure; they suffer physical breakdown relatively early in life. Even now the toll is so great among these people from tuberculosis, syphilis and the degenerative diseases that comparatively few reach old age.

Our experience thus far shows that the ratio of rates for cardiovascular lesions between white and colored men examined bears a close relation to the ratio of local mortality rates between the two races. In our studies I and II, we found that 33.5 per cent of the two groups had significant circulatory defects, while in the negro group 55.6 per cent were involved. This means that the colored rate was 1.6 times the white. The general mortality rate from circulatory diseases over a 10-year period ending 1929 averages for negroes 1.7 times that for whites. In 1930, the year during which this study was made, we find an even closer correlation in the incidence of these rates:

RATES PER 1,000 MALES OVER 20 YEARS FOR CARDIOVASCULAR LESIONS FOUND IN 3,000 EXAMINED MEN AND MORTALITY RATES FROM CARDIOVASCULAR DISEASES PER 1,000 MALE POPULATION OVER 20 YEARS IN CINCINNATI DURING 1930

	Mortality per 1,000	Cardiovascular lesions per 1,000 examined
White .....	33.0	33.5
Colored .....	55.9	55.6

In general it may be predicted, on the basis of this survey and other information, that a very large amount of physical impairment probably exists in the negro race. Moreover, the small sample on which our observations have been based shows a considerable amount of significant physical impairment in male labor groups under 40.

This situation is not without hope of improvement. We find in the recent mortality records of small groups of negroes in a higher economic class, and in favorable environment, an indication of definite improvement. Morbidity and mortality rates among negroes can, we believe, be lowered to the point where they will compare favorably with those for whites. This may eventually come to pass, but there will be many social, economic, and health problems to be dealt with in realizing the accomplishment.

# Effect of Lead Arsenate Spray on the Composition and Vitamin Content of Oranges\*

E. M. NELSON, PH. D., AND H. H. MOTTERN

*Bureau of Chemistry and Soils, U. S. Department of Agriculture,  
Washington, D. C.*

GRAY and Ryan<sup>1</sup> in California, and Juritz<sup>2</sup> in South Africa, in studying the effect of arsenic sprays on oranges found a marked reduction of acidity in the ripe fruit. Juritz also found a diminution of sucrose from 4.14 to 1.12 gm. per 100 c.c. of juice in heavily treated trees, total sugar changing only from 9.77 to 7.26 gm. per 100 c.c. of juice. In 1927 Hawkins and Barger<sup>3</sup> reported that they had confirmed the results of Gray and Ryan and stated that in 1893 it was reported to the Florida State Horticultural Society that spraying with a mixture of bisulphate of soda and arsenate of lime would produce a sweet orange.

Yothers<sup>4</sup> showed that the change in composition of the fruit is altered by a single spraying at or shortly after blossoming time. Notwithstanding the fact that the change in the chemical composition of the fruit was definitely established 10 years ago, there have been no thorough investigations dealing with the function of arsenic in bringing about a deranged metabolism of the plant. Recently Copeman, on the basis of chemical evidence, has postulated that lead arsenate appears to produce a selective oxidation in which the citric acid is oxidized in preference to cell wall material.

It seemed desirable to obtain further information with respect to the extent of chemical changes produced by different degrees of spraying and to ascertain if spraying had any effect on vitamin content of the fruit. The extensive use of arsenical sprays to prevent insect infestation in Florida at the time this work was planned made these investigations advisable. To prevent spread of the Mediterranean fruit fly into uninfested areas certain fruits were subjected to a method of processing under supervision of the Plant Quarantine and Control Ad-

fruit fly. These samples upon receipt were placed in storage at 40° F. and examined at that time and 30 and 60 days later.

As individual oranges vary somewhat in acid and sugar content, 10 fruits of average size and apparent degree of ripeness were selected from each lot, individually weighed, halved, the juice extracted and measured, and then filtered through 2 thicknesses of cheesecloth.

Soluble solids were determined by specific gravity and converted to degrees Brix. Acidity was determined by titrating 10 c.c. of the juice of each orange with standard alkali and the results were expressed as per cent anhydrous citric acid. The pH was determined electrometrically by the quinhydrone electrode. A composite sample of equal amounts of juice from each fruit was used for the sugar determinations. Sugars were determined by reduction of Fehling's solution, before and after inversion, the cuprous oxide being weighed, and the quantity of sugars present calculated with the aid of Munson and Walker's table and recorded as grams per 100 c.c.

The results of analyses made on the individual fruits are given in Tables I to VI. These show that there is a marked reduction in acidity of sprayed fruit. Heavily sprayed fruit has an acidity of about one-fifth of the normal, and medium sprayed about one-fourth. There is also a reduction in sucrose with a corresponding increase in invert sugar, the total sugar remaining the same. No changes due to processing were found on arrival of the shipment, nor did any develop on 60 days' storage.

One year later analyses were made on a second set of spray-treated fruit (Lots 7 to 10), Table VIII. All results given in this table were obtained from a composite sample made from the juice of 10 fruits. Lots 8, 9, and 10 were from the same orchard. Lot 7 was unsprayed fruit of the same variety but from a different orchard. Lot 8 had received approximately the same spray treatment as Lot 9 received the previous year, but no spray treatment during the current year of growth and ripening. This lot shows an almost complete recovery as indicated by the acidity and the Brix acidity ratio. The ratio of sucrose to total sugar given in the last column of this table shows the decline in sucrose according to the severity of the spray treatment. Lot 9 came from trees which had received a medium spray treatment in 1929 and in 1930, and Lot 10 was obtained from trees heavily sprayed both years. These lots show the same characteristics as Lots 3 and 5, respectively. There is a decrease in acidity with a corresponding increase in pH value and an increase in invert sugar at the expense of sucrose.

Samples of the juice and pulp from the heavily sprayed and unsprayed oranges were examined for arsenic by the Gutzeit method, but this was not present in more than the mere traces present in most food products.

Since there was a significant difference in the pH value, the effect of the juice from sprayed and unsprayed fruit was tried upon congo red paper. It was found that all the unsprayed fruit gave an acid re-

action against about 1 of 10 of the sprayed. The juices affecting congo red paper had an acidity of 0.4 per cent or greater, corresponding to a pH value of 4.4 or less. The reaction of the juice to congo red paper suggests a simple way of testing for reduced acidity in oranges due to spraying.

The total ash of sprayed and unsprayed fruit was 0.43 gm. per 100

c.c. of juice in both. The alkalinity of the ash was the same in both—the ash from 100 c.c. of juice neutralized 44 c.c. of tenth-normal acid.

#### BIOLOGICAL INVESTIGATIONS

The marked effect of lead arsenate spraying upon the chemical composition of orange juice and consequent changes in the metabolism of the plant suggested the possibility of a change in vitamin C content. The feeding of orange juice to infants, particularly those artificially fed, is a well established practice, and it is therefore very desirable to know if any appreciable variation in the vitamin C content of oranges exists. Experiments were conducted on some of the fruit used in chemical analyses. Young guinea pigs, weighing with some exceptions from 275 to 300 gm., were kept in individual cages and fed a ration of rolled oats, 69 parts; alfalfa meal (autoclaved  $1\frac{1}{2}$  hours at 15 lb. pressure), 25 parts; commercial casein, 5 parts; sodium chloride, 1 part. The desired dose of orange juice was fed daily with a pipette. The animals were weighed twice a week and observations of their condition recorded at each weighing or oftener.

Three experiments were conducted, 2 in the winter of 1930, on different levels of the same orange juice and 1 in the winter of 1931. The first experiment was with 1 c.c. of orange juice per day from fruit that had not been sprayed (Lots 1 and 2), and from fruit of trees sprayed heavily with lead arsenate (Lots 5 and 6). Six animals were put into a control group and received no vitamin C. Twelve animals were fed the normal orange juice, and 12 the juice from sprayed trees. Two of the last died within a few days and are not considered in analyzing the results. The average weight changes of the animals in each group are shown in Figure 1, Groups 1, 2 and 3. From this it is apparent that the growth promoting effect of orange juice when it supplements a vitamin C deficient ration is greatly impaired by spraying with lead arsenate.

The animals in Group 1 lived an average of 18 days, ranging from 14 to 22. All of them showed symptoms of scurvy on the 12th day. All except 1 in Group 3 showed some symptoms of scurvy by the 15th day, 2 died, 1 in 20 days, and 1 in 26 days, after the experiment was begun. In Group 2, 4 animals developed scurvy by the 15th day, 1 in 19 days, 5 in 22, 1 in 26, and 1 in 28. There was, therefore, a marked delay in the onset of scurvy in the animals receiving the juice of fruit from unsprayed trees. Autopsy findings were confirmatory of the observations on the living animals. The experiment was discontinued at the end of 7 weeks. All of the animals showed extensive scorbutic lesions, but looseness of the teeth and brittleness of the bones

was considerably more pronounced in Group 3 than in Group 2.

The second experiment was begun 1 month after the first, using the same number of animals and the same orange juice, but  $1\frac{1}{2}$  c.c. of juice were fed daily. The growth response of these animals was distinctly better than with 1 c.c. of juice (Figure I) but growth on the normal juice was superior to that from the sprayed fruit. There was a greater difference with respect to onset of scurvy. The controls, Group 4, developed scurvy in 12 to 15 days and lived an average of 23 days. All the animals receiving the juice from sprayed trees (Group 6) showed some symptoms of scurvy by the 18th day and their condi-

FIGURE I—These graphs show that when guinea pigs are fed orange juice as a sole source of vitamin C the growth response is greatly influenced by the quality of the juice as affected by spraying orange trees with lead arsenate. Group 1 received only the scorbutic ration. Groups 2 and 3 received 1 c.c. of orange juice daily from the fruit of unsprayed (oranges Lots 1 and 2) and heavily sprayed trees (oranges Lots 5 and 6), respectively. There were 6 animals in Group 1, 12 in Group 2, and 10 in Group 3. Groups 4, 5 and 6 are, respectively, duplicates of Groups 1, 2 and 3 with the orange juice fed at a  $1\frac{1}{2}$  c.c. level daily. There were 6 animals in the negative control, Group 4, and 12 in each of Groups 5 and 6. Eight animals were started in each of the remaining groups, but 1 animal in Group 8 and 2 in Group 11 died within a short time and are not included in the compilation of results. Group 7 received no vitamin C. Oranges from trees treated as follows were used in the remaining tests: Group 8, oranges Lot 7 not sprayed. Group 9, oranges Lot 8 medium-sprayed, 1929; no spray, 1930. Group 10, oranges Lot 4 medium-spray, 1929 and 1930. Group 11, oranges Lot 10 heavily sprayed, 1929 and 1930. There was no difference in growth of the animals, depending upon whether the trees had received heavy or medium spray treatment. Some effect of the spray treatment in 1929 was evident even though there was no spray during the year the fruit was grown.

tion remained about the same until the experiment was discontinued at the end of 8 weeks. Only 2 of the animals receiving normal juice (Group 5) developed scurvy, 1 in 17, and 1 in 28 days.

We were interested in any possible detrimental effect of processing mentioned and our investigations were planned to obtain information on this point. In the experiments just described 30 animals were di-

vided into 5 equal groups. Group 1 received no vitamin C, while the others received orange juice as follows: Group 2, normal oranges, unprocessed; Group 3, normal oranges, processed; Group 4, oranges from heavily sprayed trees, unprocessed; Group 5, oranges from heavily sprayed trees, processed. Processing had no demonstrable effect on vitamin content of oranges irrespective of whether the trees were

sprayed or not. For the purpose of discussing the effects of spraying, the animals have been regrouped without reference to whether the fruit was or was not processed.

The third experiment, carried out in 1931, was designed to obtain more accurate information on the effect of different degrees of spraying on vitamin content of the fruit. Forty animals were divided into 5 equal groups. Group 7 received no vitamin C, and Group 8 received normal orange juice; the remaining received orange juice from trees which had the following treatment: Group 9, no spray in 1930 and medium spray in 1929; Group 10, medium spray in 1929 and 1930; Group 11, heavy spray in 1929 and 1930. The growth of the animals (Figure I) is in fairly good agreement with the chemical findings. The effect of spraying in 1929 is evident though there was no spraying

the year the fruit matured. There was no demonstrable difference between the fruit from medium and heavily sprayed trees. The negative control group developed scurvy in an average of 14 days and survived an average of 22 days. No scurvy was observed in Groups 8 and 9 and only slight evidence of it was revealed by autopsy. There were 2 cases of marked scurvy in Lot 11, 1 in 28 and 1 in 42 days. There were 4 deaths in Group 10 after the 5th week. All of the animals in Groups 10 and 11 showed extensive lesions of scurvy upon autopsy.

#### DISCUSSION

The ratio, Brix to acidity, is used in determining the degree of maturity of citrus fruits intended for interstate shipment. By means of the Brix spindle the total soluble solids of the juice are determined. Acidity is calculated as anhydrous citric acid from the titrable acidity. The Brix acidity ratio is obtained by dividing the percentage of total soluble solids by the percentage of citric acid. The value of this ratio increases as the ripening of the fruit progresses. The minimum values set by maturity standards based on this ratio are reached earlier by the use of arsenical sprays. This fact has been taken advantage of

by unscrupulous fruit growers to market their fruit early in the season when better prices may be obtained.

It seems desirable to make it clear that there is little danger of consumption of arsenic when eating fruit from sprayed trees. Furthermore, citrus fruits normally receive a cleansing treatment before being placed on the market. While this might not remove all the residue in the pores of the peel, the remainder would be discarded with the peel or in extracting the juice. There is no detectable increase in arsenic in the juice or pulp of oranges from sprayed trees over that found in those from unsprayed trees.

The changes in chemical composition of oranges due to spraying assume greater significance in the light of the low vitamin content of such fruit since the chemical changes involved may be much more extensive than those recorded to date. The changes known to take place in citric acid and in sugar content do not alter appreciably the nutritive value of the fruit. However, oranges are a very important source of vitamin C and the decrease in this factor is worthy of serious consideration. Fortunately, both California and Florida have laws preventing the use of arsenical sprays on citrus fruits. These laws were designed to protect the citrus fruit industry by preventing the sale of immature fruit that meet the standard necessary for interstate shipment. Our findings on the lessened nutritive value of sprayed oranges now add an important additional reason for the enforcement of these laws.

These investigations indicate that the Brix acidity ratio can be used to indicate low vitamin C content of orange juice. Further study should be made to determine to what extent the high Brix acidity ratio can be correlated with low vitamin C content. We conclude from the experiments that have been completed that the vitamin C content of heavily sprayed oranges is decreased fully one-third and it may be only one-half of that of unsprayed fruit.

Owing to the widespread use of arsenical sprays to combat insect pests, the observation that lead arsenate adversely affects the vitamin C content of oranges opens up a new field of investigations. Additional studies involving the effects of various sprays upon the vitamin content of fruits and vegetables are being planned.

#### SUMMARY

Data are presented to show that oranges produced by trees sprayed with lead arsenate differ in chemical composition from normal oranges. The most pronounced difference is a reduction in acidity of the juice; there is also a decrease in sucrose with a corresponding increase in invert sugar.

The arsenic content of the edible portion of the orange was not changed by spraying the tree with heavy doses of lead arsenate.

The vitamin C content of oranges from trees sprayed with lead arsenate was found to be considerably lower than that of oranges from unsprayed trees of the same variety and the same degree of maturity.

The processing of oranges as practised by Plant Quarantine and Control Administration to destroy larvae of the Mediterranean fruit fly did not change the character of the sugars, citric acid or vitamin C content of the fruit.

# Public Health Aspects of Frozen Foods\*

CARL R. FELLERS, PH. D., F. A. P. H. A. (*Life Member*)

*Massachusetts State College, Amherst, Mass.*

THE phenomenal growth of the frozen food industry in the United States and the British Empire during the past few years may well cause public health officials to inquire into its public health aspects. Statistics for 1930 show a production in the United States of 320,000,000 gal. of ice cream, 77,000,000 lb. of poultry, 30,000,000 lb. of strawberries, 100,000,000 lb. of fish, and correspondingly huge quantities of meats, fruits, and other products. That the industry will grow in the future is certain. At present we are in a stage of flux and experimentation. New products are being frozen, new and improved equipment and processes are being developed, and the thermodynamics and mechanical phases of freezing are becoming better understood.

Freezing as a means of preserving perishable food is not new. The Greeks and Romans were thoroughly acquainted with the preserving action of cold. As long ago as 1860 in Australia, Morris and Mort<sup>1</sup> are said to have been the first to freeze successfully and export beef and mutton to England. Piper<sup>2</sup> in Maine was the pioneer in commercial fish freezing in 1861. Similarly, frozen eggs and poultry have been staple commodities since before 1900. The addition of fruits, filleted fish, meat cuts, and vegetables to the list of frozen foods is much more recent. Though packed experimentally in 1912, fruits were first frozen commercially in the Pacific Northwest about 1918.<sup>3</sup> The production of all varieties of frozen berries, peaches and cherries has reached tremendous totals comprising a considerable percentage of the crop. It cannot be said even now that frozen vegetables are commercially successful. The successful launching of new foods depends upon research, advertising, and the repeat orders of the consumer.

The food habits of a nation cannot be changed overnight. Frozen foods must compete with fresh grown, shipped-in, canned, dried, salted, and smoked products. The capacity of the human stomach does not change. When we eat frozen fish, we buy less fresh fish. In time the

---

\* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 14, 1931.

public will learn which foods are best canned, which are best frozen or otherwise preserved. It is almost axiomatic that no preserved foods will wholly substitute for the fresh, though for the sake of convenience, dietary variety, and nutritional balance, they will always find a ready market. It is certain that the public will prefer frozen perishable foods of good quality if the cost is reasonable, to low quality or unattractive fresh foods.

The economic advantages of frozen foods should be briefly mentioned. Especially such perishable ones as fish, meats, and fruits are prepared at central points where available. Waste and inedible parts are removed. Transportation charges are less and the foods do not deteriorate greatly in storage. Freezing utilizes perishable crops, stabilizes industry, prevents waste, and facilitates marketing. Frozen foods are convenient to handle, require little space and make an attractive display. The shopkeeper likes them because he can readily figure his profit as in other packaged goods. Optimists in the industry predict that the time is not far distant when a large percentage of the 400,000 grocery stores in the country will handle packaged foods.

#### GENERAL HEALTH ASPECTS

In what ways can this huge new industry affect the public health? The following factors seem to have some bearing on the question.

1. Sanitation and working conditions at the freezing plants
2. Freshness and soundness of raw materials
3. Effectiveness of the process, its controllability and dependability
4. Effect of freezing and storage on quality, chemical, and nutritive values
5. How does freezing and storage affect bacterial population of the food?
6. What happens when frozen foods are thawed and how long after defrosting do they remain safe to eat?

#### SANITATION AND WORKING CONDITIONS

The writer has had the opportunity of inspecting a considerable number of freezers for the handling of meats, fish, poultry, fruit, in plants located in the East, West, and South. With very few exceptions, there are only minor sanitary problems. Since nearly all freezers are located in cities, modern plumbing and sewage disposal systems are available. In general, fish, meats, and poultry are prepared for freezing in clean surroundings.

Birdseye,<sup>2</sup> and Tressler,<sup>4</sup> have described the really excellent sanitary measures which have been adopted by some of the largest plants. Their investigations showed a progressive reduction in bacterial numbers as the fish were washed, skinned, filleted, and packaged for freezing. Titman<sup>5</sup> also described the effective sanitary measures in use in

modern egg freezing plants. Ample clean water is usually at hand, while fairly good lighting and ventilation systems are the rule.

The use of chlorine and hypochlorite in the washing waters and brines in some plants is a highly commendable practice. Because of the fact that foods to be frozen are often kept many months before being sold and consumed, the quality of the raw material is carefully watched. It is thoroughly understood by the trade that poor quality, or semi-spoiled fish, poultry, fruit or eggs cannot be improved by freezing. In fact, operators recognize that the quality of such foods is very likely to become poorer during freezing storage and sometimes they become tainted and unfit for human consumption when thawed out. The activity of the federal and state food officials in carefully inspecting frozen foods, both at the time of packing and while in storage, also acts as a strong deterrent against the use of poor quality raw products.

Working conditions in the plants compare favorably with those in other industrial establishments such as canneries. Limited data collected at several cold storage or freezing plants do not show any greater incidence of respiratory disease among workers than is normal for the community. I believe we can truthfully state that plant sanitary standards are relatively high. One reason for this is that many owners and operators of freezers are unusually progressive, intelligent, and public minded.

#### RAW MATERIALS

The absolute necessity of using only first quality raw products for freezing is fully recognized. Formerly, unscrupulous dealers sometimes resorted to freezing poultry, fish, or meat which was in an incipient stage of decomposition, but repeated losses, frequent seizures by the state and federal officials, and a general lack of interest in such foods by the trade, have caused this shady practice to be abandoned.

To more than any other single factor, the general lack of public faith in frozen foods has been due to their uncertain quality. It has been a hard fight to persuade the people that frozen meats, fish, eggs, poultry, fruits, and vegetables can be nearly as attractive and fully as sound, palatable, and nutritious as when fresh. In justice to modern progressive operators, much praise must be given them for the extreme care they are now taking to guard the high grade and soundness of their packs.

In the freezing of foods there is no excuse for delay, which brings on deteriorative changes. Berries must be free from mold, fermentation, and dirt. Fish and other marine products must be thoroughly cleaned, uncontaminated with fecal bacteria, and free from odor or

even incipient spoilage. Meats must be subjected to the usual federal inspection for evidence of disease or other conditions which might render them unfit for human consumption.

Some municipalities require inspection of poultry as well as meats. Some years ago in the Pacific Northwest it was customary to freeze lower grades and soft berries that could not be marketed fresh or sold to the canneries. Is it any wonder that frozen pack fruit bore a poor reputation? It can now be said that at least average quality raw products are used for the modern frozen pack of all foods.

#### EFFECTIVENESS AND DEPENDABILITY OF FREEZING

It is outside the province of this paper to discuss the relative merits of various freezing systems or methods. Several commercial processes now in use are strictly dependable and effective. We hear a great deal about "quick-freezing." This catchword has been over-emphasized. To the layman it means some special new method, by which the food is frozen in a few seconds or minutes at most. The truth is that many successful methods are being used to freeze foods with reasonable rapidity, but even the so-called "quick-frozen" foods, in very small packages or cartons, require an hour or more. No satisfactory methods of freezing large quantities or pieces, such as carcasses of beef, have been devised.

There is a growing tendency to freeze at lower temperatures than formerly. The usual range for rapid freezing is from 0 to 40° below zero F. Since most foods contain from 70 to 95 per cent of water, they begin to freeze at about 32 to 25° F. In lowering the temperature from 32° to 15° F., about 85 per cent of the water of a food crystallizes as ice; at 0° F. approximately 95 per cent of the water is frozen. When water separates as ice there is a gradual increase in concentration of the remaining liquid. This renders freezing increasingly difficult as the amount of free moisture diminishes. Complete freezing of the water takes place at temperatures of 60 to 100° below zero F. in most foods.

Slow freezing in air produces slow growing, large ice crystals in the intercellular spaces. Sharp or rapid freezing of flesh foods produces crystals only in the muscle fibers themselves and not in the intercellular spaces. Such foods thus retain their former appearance upon thawing.

Planck, Ehrenbaum and Reuter<sup>\*</sup> in 1916, conducted some of the first experimental work on the effect of freezing on foods, especially fish. They conclusively demonstrated the greater efficacy and desirability of rapid freezing at low temperatures in so far as the physical, histological, and chemical character of the frozen or thawed product

was concerned, and showed the necessity of a controlled, even, low storage temperature in order to avoid deteriorative changes. A good summary of the changes occurring during freezing and thawing is given by Glennie<sup>7</sup> and Planck.<sup>8</sup>

It is untrue that large ice crystals formed in slow freezing are the main cause of the exudation or "drip" of juice in frozen flesh foods. Though laceration of the cells may occur, this is not the primary cause of leakage, notwithstanding popular opinion to the contrary. Leakage or drip in frozen foods causes the loss of valuable extractives and salts, and should be eliminated if possible. The cause is a more or less irreversible flocculation or coagulation of colloidal gels of which cells and protoplasm consist. Modern methods of rapid freezing have been developed which largely prevent leakage in meat and fish upon thawing. Leakage in plant products, however, cannot be overcome because of fundamental differences in the composition and gel structure of the plant cell.

The cell contents of both plants and animals consist of a colloidal gel containing proteins, salts and water. When the water is frozen the gel structure or network is broken down. In the case of flesh, the colloidal gel structure is largely reversible and when frozen meats or fish are thawed, the cells reabsorb most of the water. That is, flesh foods retain their structure and texture better than plants. The cell walls of flesh are highly elastic; those of plants are composed of cellulose and pectins and are inelastic. In fruits and vegetables the gel being irreversible, cell walls rupture, water is not reabsorbed after thawing, and the fruit or vegetable loses its turgidity and original firm structure. For full discussions of the physical effects of freezing tissue see Taylor,<sup>9</sup> Birdseye,<sup>10</sup> Woodruff,<sup>11</sup> Magoon,<sup>12</sup> and Joslyn.<sup>13</sup> The addition of sugar to fruits greatly aids in preserving the original characteristic flavor and color. Diehl,<sup>14</sup> Fellers and Mack,<sup>15</sup> Joslyn and Cruess,<sup>16</sup> and Woodroof<sup>17</sup> have investigated the freezing of fruits with and without sugar for use in ice cream, jams, juices, and for table consumption. While fruits were originally frozen exclusively in 50 gallon barrels, the use of smaller containers suitable for the retail trade, such as hermetically sealed and slip-on covered tin cans, glass jars, waxed paper cups, and cartons, and cellophane packages for a wide variety of products is increasing.<sup>10, 17, 18, 19, 20</sup>

It has been proved that frozen foods dry out considerably and lose weight during storage.<sup>20</sup> There is also a tendency for fats to oxidize and become rancid and for "rusting" to occur. This "rusting" has been shown by Taylor<sup>21</sup> to result from a change of hemoglobin to methemoglobin. Enzymic oxidations sometimes produce surface dis-
